ENDOMETRIAL HEMATOMAS OF THE OVARY.

By J. V. MEIGS, M.D., BOSTON.

In the *Archives of Surgery* for September, 1921, Dr. John A. Sampson,¹ of Albany, N. Y., published a paper which is the foremost contribution to gynecology and gynecological pathology in recent years. The title of his paper is "Perforating Hemorrhagic (Chocolate) Cysts of the Ovary: Their Importance and Especially Their Relation to Pelvic Adenomas of Endometrial Type (Adenomyoma of the Uterus, Rectovaginal Septum, Sigmoid, etc.)." His paper explains very completely the so-called chocolate cysts, blood cysts, and hemorrhagic cysts so often found in pelvic operations. These cysts were usually considered to be of corpus luteum, follicular, or stromal origin.² Sampson has shown that some of these cysts are due to menstruating endometrial-like tissue in the ovary; that is to say, cysts which are found to be densely adherent, and which burst, permitting the escape of chocolate or tarry fluid when released, may contain endometrial-like tissue. In his article he reports that all of his cysts had at some time ruptured, and that on examination, after removal, the site of the perforation could always be found. (This last statement he no

longer holds to be true.) In most cases there is a small perforation, and dense adhesions are found in the pelvis, especially about the ovary. The endometrial-like tissue is found in various places in the ovary and in various forms, but usually it is near the perforation, and may be in the form of glands composed of columnar epithelium with an undifferentiated connective tissue stroma. Other specimens show a cuboidal, columnar, or cylindrical epithelium resting upon a thin layer of cellular tissue containing many blood vessels, and extravasated new and old blood. Still others have one of the above types of epithelium resting upon a thick layer of fibrous tissue, or even directly upon the ovarian tissue itself. The most important finding is the presence of hemorrhage, and especially the signs of old hemorrhage in a cyst wall lined with epithelium, which is not stratified. The sign of old hemorrhage is blood pigment (hemosiderin) chiefly in endothelial leucocytes, the presence of blood pigment, meaning that hemorrhage has occurred at some previous time. The blood remains in the tissue beneath the epithelium, because it cannot escape as does hemorrhage in the uterus or in the kidney, which have a passage to the outside of the body. The presence of blood pigment in the ovary is comparable to hemorrhage in the liver or spleen. The blood cannot escape, so it changes to blood pigment, and is later gathered up by endothe-

al leucocytes whose function it is to remove foreign bodies of this type. The diagnosis under the microscope is made by the presence of tissue definitely resembling endometrium, or by finding a cyst with a wall that is comparable to a dilated gland found in adeno-leiomyomata containing blood. Before the diagnosis can be accurately made the entire case must be considered, history, physical findings, operative findings, the appearance of the cyst, and its histology. Further, he has shown that these cysts are capable of implanting early adenomas of endometrial type on the peritoneum at the site of adhesions about the perforation. He has also found dark blue blebs at distant portions of the pelvic peritoneum, which histologically are cysts full of blood, and comparable to dilated glands in adeno-leiomyomata. Some of these small cysts grow and invade the tissue upon which they are implanted. Sampson believes, and we believe has proved, that adeno-leiomyomata of the Fallopian tube, of the round ligament, of the posterior wall of the uterus, of the posterior surface of the broad ligament, of the sigmoid, and also of the small intestine and appendix, are in some instances the results of implants from these cysts. The new adenoma may be due to direct extension from the cyst at its site of perforation, or to minute seed implants falling from the endometrial-like tissue at the time of perforation of the cyst. Thus a new explanation has been given for the presence of some of the various adeno-leiomyomata found throughout the pelvis in woman. His article gives an explanation for the many cases of severe pelvic inflammation, the etiology of which has been so obscure and puzzling heretofore.

CONFIRMATION OF SAMPSON'S ARTICLE.

Wishing to confirm the existence of these interesting hematomas we have searched through the records of the Free Hospital for Women, Brookline, Mass., and the records of Dr. William P. Graves of Boston. A careful study has also been made of the pathological records, and the specimens preserved in the hospital laboratory. It has been the custom of the hospital, and of Dr. Graves, since 1903, to preserve in formalin all gross specimens removed at operation; thus it has been possible to discover numerous cases which otherwise would have been lost. The original microscopic slides of the specimens were of help in but three or four instances. When the history, physical findings, operative findings, and description of the specimen suggested the presence of an hemorrhagic cyst of the ovary, the tissue was recut and new microscopic slides made.

The series of cases reported confirm Sampson's findings in a large degree. The cysts, themselves, grossly and histologically are as he describes them. They measure from 1 cm. to 12 cm. in diameter, but usually they are not

larger than 4 cm. A cyst 12 cm. in diameter was the only large one found. It was not suspected at operation, but the microscopic sections showed definite endometrial-like tissue in its walls. The location of these cysts is on the lateral surface or on the free border of the ovary. No cyst has been found on the median wall in this series. Perforation and adhesions about the ovary have been found in all cases seen since the publication of Sampson's article except one, this one being the large cyst described above, which had no perforation but was adherent. In the specimens that were recut the question of perforation was abandoned, because in all the cases the ovary had been sectioned in such a way as to make an accurate observation impossible. The contents of the cysts were typical in every case: dark, chocolate-colored or tarry fluid. In most of these cases the endometrial-like tissue could be recognized easily. In some it was necessary to make the diagnosis on the appearance of the cyst wall. These walls are characteristic of certain areas in nearly all endometrial hematomas of this type. There is a layer of cuboidal, columnar, or cylindrical epithelium resting upon a tissue composed of blood vessels and loose connective tissue, with both extravasated new and old blood in abundance. The diagnosis of this type of cyst is not difficult provided the history, physical findings, operative findings, and cyst contents coincide with Sampson's description.

The question of peritoneal implantation has been verified in but one case microscopically. In this case there was an adeno-leiomyoma of the posterior wall of the uterus near but not touching the adherent endometrial hematoma of the ovary. The tip of the appendix was adherent to the cyst and showed on section glands and stroma resembling endometrium in its walls. The condition is also well described in the operative notes in some of the older cases. In two cases there were adeno-leiomyomata in the left cornu of the uterus, and in one case undoubted adeno-leiomyomata in the sigmoid. The explanation of our inability to confirm him in more cases is that in only four cases was the nature of the cyst recognized at operation and of these but one showed implantation. In the other cases the cysts were not recognized so that no tissue of this kind was removed.

ETIOLOGY.

There are various theories explaining the etiology of these cysts and there is some support for them all. In his paper Sampson offers the following suggestions, among others:—

1. That the cysts may be endometrial from the beginning of their existence.
2. That certain parts of the germinal layer of epithelium of the ovary are able to undergo a metaplasia and take on the function and

histology of endometrium. In some of the microscopic slides of the cases reported in our paper there is a suggestion of this. That is, a short distance below the germinal layer of epithelium there may be a few so-called "gland inclusions," and directly below them the endometrial-like tissue. Serial sections were not made to show their continuity but the presence of gland inclusions near the endometrium raises the question as to whether this may not be the true etiology.

3. That "cell inclusions" in the ovary may be of endometrial origin and may reline an ovarian hematoma after its rupture and discharge of its contents. In this series there have been two cases seen lately in which the cysts were not lined with epithelium except at the site of perforation and a short distance into the cyst proper. The rest of the cyst strongly suggested one of corpus luteum origin.

4. On February 14, 1922, at the Peter Bent Brigham Hospital, Boston, Sampson suggested as another theory for the formation of these cysts, that they are due to the implantation of endometrium reaching the ovary by way of the Fallopian tube. He compared the location of the cysts, of the early adenomas of endometrial type found on the peritoneum, and that of pelvic adeno-leiomyomata with the location of inflammation in the pelvis due to the gonococci. The gonococcus finds its way into the pelvis through the uterine cavity and the Fallopian tube. It attacks the tube, ovary and pelvic peritoneum. Endometrial hematomas are likewise found in the same locations. He has found small growths of endometrial-like tissue on the pelvic peritoneum without the presence of an endometrial hematoma in the ovary. Therefore, if the gonococcus can be carried from the cervix to the tubes, ovaries, and pelvis, why is not the same process possible for the small bits of endometrium? The ovary being in contact with the fimbriae of the tube would be the first structure to be touched by the endometrium after leaving the tube. Perhaps the ovary, in addition to being the stimulator of these cysts, may also act as an incubator and nourish the small bits of endometrium as they make their way into a ruptured follicle or cleft. Two cases mentioned by Dr. Frank B. Mallory, pathologist at the Boston City Hospital, seem to support the theory of transplantation of endometrium. There were cases in which adeno-leiomyomata were found in abdominal scars following normal Caesarean sections. Here it is possible that the endometrium was transplanted to the abdominal wall at the time of section of the uterus.

5. Janney attempts to account for the presence of endometrial-like tissue in the ovary embryologically. The material for his paper was obtained in the laboratory of the Free

Hospital for Women in Brookline, Mass. In this report of cases we have used the three specimens which he found and studied. In his work, done before the appearance of Sampson's paper, he suggests that uterine tissue in the ovary is much commoner than it was previously supposed to be. His theory suggests that uterine tissue found in the ovaries may be due to a developmental defect. The funnel, the earliest beginning of the Müllerian duct, may develop on the median instead of on the lateral side of the tubal area from which the ovary arises. Tissue may become mixed when these two areas are close together, and thus tissue capable of forming endometrium may be included in the ovary, to develop later in life. If this is so, the question has been raised as to why endometrial tissue is never found in the testicle. We believe the reason to be that the ovary is necessary to stimulate endometrial tissue to activity and that without an ovary the tissue shrinks and atrophies.

6. Russell¹ says that the epithelium of the uterus, tubes, and germinal epithelium of the ovary are all derived embryologically from the same place and that therefore it ought to be possible for the same tissue to develop in any one of these organs.

A THEORY CONCERNING THEIR GROWTH.

Because these cysts cause dense adhesions, are the forerunners of adeno-leiomyomata, and are invasive, the questions will be asked, why are they not more serious? Why do they not cause more frequent serious damage? Sampson says that 10 per cent. of all women who have abdominal operations will show this pathology. We believe the explanation of this to be that the cysts develop very slowly. This is suggested by the fact that they usually do not appear until the patient is over 30 years of age; in other words, they are not found until 13 to 19 years of menstrual life have passed. We have found these cysts in younger women, but have not seen one in a woman younger than 24. This fact is surely suggestive of slow growth. The fact that they are made up of endometrial-like tissue and that they have the power of menstruating like normal endometrium is also suggestive of slow growth. For the cyst contents increase at every menstrual period, and as the menstrual life of woman is from 30 to 35 years, if the endometrial-like tissue and the cyst contents did not develop slowly they would soon be very large. The same reasoning holds true for the implantations from these cysts, as they are composed of the same type of tissue.

The cysts are influenced by the menstrual function, and in all cases signs of menstruation are present. In some cases the menstrual stage of the endometrial-like tissue is in the

same stage as the endometrium of the uterus, and in others it is not. The cysts are rarely found after the menopause; Sampson reported none. There are two cases in this series occurring after the menopause, and in one of them the endometrial-like tissue is very scarce and evidently atrophying. The cyst in this case is without doubt an endometrial hematoma because of the adhesions to the broad ligament, its site of perforation, its content of chocolate-like syrup, and its scanty but evident layer of columnar epithelium upon a wall that contains much old blood pigment in endothelial leucocytes. Here the cyst is retrogressing because, the menopause having occurred, ovarian stimulation is absent, and the endometrial-like tissue in it has atrophied as does the endometrium of the uterus.

We believe that as the endometrium of the uterus is governed by the ovarian secretion, so the endometrial-like tissue of these cysts is governed by it. If both ovaries are removed the catamenia cease and the activity of these cysts ceases also. They then stop growing and slowly atrophy. We do not know if they disappear altogether, but they become smaller and of no importance. Case No. 8946, reported below, is an example of the shrinking of the tumor after castration. Although the tumor could not be felt after two years, it was in all probability present microscopically.

QUESTION OF STERILITY.

Why are the cysts more common in nulliparous than in parous women? The same laws that govern the ovary and uterus govern these cysts also. Women who bear children usually marry before 30, the age at which these cysts are first found. If the cyst is bilateral, or has perforated and become adherent, causing pelvic adhesions and pulling the uterus into retroversion or retroflexion, the probability of pregnancy is slight. Provided the cyst has progressed to any extent the woman married after 30 will often be sterile. If, on the other hand, there is a microscopically small or non-adherent cyst present, and the young woman marries and has a child, the cyst may atrophy and perhaps even disappear in the stage of lactation atrophy which the genital tract frequently undergoes during the nursing period.* If it disappears it will not return, but if it has atrophied and is smaller it has lost many of its remaining menstrual periods during the time of pregnancy and nursing, and will have to start to grow again at a much later period of life than that at which it normally should com-

mence. This would tend to keep its size very small, and each succeeding pregnancy and nursing period would repeat the process of atrophy. In connection with this it is a fact that the cysts are commoner in women who have borne few children than in those who have borne many. Inasmuch as the percentage of multiparae operated upon is greater than that of childless women, or primiparae, this theory is further supported. Otherwise, if these cysts are likely to occur in all women, more of them should be found in parous women.

The above theories of slow growth and the reasons for the cysts being prevalent in nulliparae and rare in multiparae are not contradicted by any of the theories of the possible etiology of the cysts and the derivation of the endometrial-like tissue. It would be interesting to note in the histories of these cases whether the women who have children and who also have had an endometrial hematoma did or did not nurse their children. Unfortunately this fact is not stated in our histories.

CLINICAL STATISTICS.

In this series of 16 cases it is interesting to consider a few statistics. Fourteen women were married and two single. Of the married women, five had children and nine did not. One had five children, two had two, and two had one child. This is consistent with what Sampson writes concerning the frequency of sterility.

There were five patients in the 20 to 30 decade, eight in the 30 to 45 period, and three over 45, two of whom had had the menopause. These figures are consistent, only two cases being below 25 and most of them over 30. It is true, therefore, that women usually have from 13 to 19 years of menstrual life before the presence of the cyst becomes known.

The histories given by these patients are not always of diagnostic value, although in Sampson's series certain features, such as acquired dysmenorrhea, and constipation, worse at the menstrual period, were frequently present. The histories and the physical findings taken together should suggest the presence of an endometrial hematoma. Five of our patients complained of dysmenorrhea, one of acquired dysmenorrhea, four of menorrhagia of recent origin, and six of indefinite abdominal pain. Two patients had palpable tumors, and one complained of sterility. One of the cases with a palpable tumor had a malignant papillary cyst adenoma of the opposite ovary from that in which the endometrial hematoma was located, and the other had an endometrial hematoma of the ovary that was palpable. One case noticed increasing pressure in the rectum, and operation showed a cyst impacted in the pelvis behind a retroverted uterus. Indefinite lower

*Occasionally, in women who, in their children, the uterus may undergo excessive involution, becoming smaller than in the virgin state. It is probable that the cessation of menstruation, which is usually observed during lactation, should be attributed to the form of atrophy. In some instances the atrophy may persist after weaning and become permanent, the uterine cavity shrinking back into only a few centimeters in length. (1906 letters.) Williams.

abdominal pain, dysmenorrhea and menorrhagia were the most common symptoms in this series.

The catamenial history is of some importance. Eight cases had normal and regular periods; four flowed more than normal at their periods. One case nearing the menopause flowed irregularly every three to six months, while two others had had the change of life. One other case was regular every six weeks.

We feel that although the histories are important, they are not suggestive, except in very few cases, without the presence of the physical findings and pelvic examination. All of the cases were examined by Dr. W. P. Graves, and the results of his examinations are tabulated as follows:

Retroversion or retroflexion with a palpable mass	6
Retroversion or retroflexion with adhesions	2
Retroflexion	1
Anteflexion with lack of mobility	1
Normal position of uterus with mass in left cornu	1
Normal position (to have repair of umbilical hernia)	1
Pelvic inflammation	1
Abdominal tumor	1
Fibroid	1
Atrophied uterus (to have dilatation and curettage for diagnosis)	1

In this series, then, all examined by one surgeon, typical findings such as retroversion, or retroflexion with a mass or adhesions, and one with anteflexion with lack of mobility, were found in nine cases. The results of these examinations, coupled with the histories, should at once suggest the probable presence of an endometrial hematoma of the ovary, if gonorrhea has first been ruled out. Since the appearance of Sampson's article, the case diagnosed as pelvic inflammation would probably suggest a case of this type, if there were no history of gonorrhea. We therefore think the diagnosis should be made in about 50 per cent. of the cases, but doubt if it could be in a higher per cent.

TREATMENT.

The operative procedures in the four cases recognized at the operation as hematomas of the ovary were as follows: In the first case the right ovary was removed after the adhesions were broken up, but no sign of implants on the peritoneum were found, although carefully looked for. The second case was of the same nature and the left ovary was removed. The other ovary was normal and no implantations were found. In the third case, a supravaginal hysterectomy, with coring out of the cervix, was performed for adenocarcinoma of

the fundus, and both ovaries removed. The right ovary contained an endometrial hematoma and no peritoneal implants were found. In the fourth case, the right ovary was removed, and also a small leiomyoma and the appendix. Implantation was found in the leiomyoma and appendix but was not recognized as such at operation. The operation should depend upon the extent of the disease and the question of peritoneal adenomas of endometrial type. If the cyst and all the suggestive areas in the peritoneum cannot be removed, a supravaginal hysterectomy with bilateral salpingo-oophorectomy should be done. For if ovarian tissue is left behind, the endometrial tissue will continue to be stimulated and will grow. If, however, all the endometrial tissue, including the cyst, can be removed, or if there are no peritoneal or other implantations, we believe it is best to resect the cystic ovary, if possible; or, if not, remove it, and leave the patient her other genital organs. For if all the endometrial tissue can be removed there will be nothing left for the ovary to stimulate, and the patient should be cured. Conservatism should prevail if all the endometrial tissue can be removed, for the growth is probably very slow and seldom endangers life. If, however, all the endometrial-like tissue cannot be removed, the operator should perform the radical operation, for if it is not done the patient will not be cured. If the patient desires children, and the disease has not made pregnancy impossible, we believe the operator should err on the conservative side, for the small adenomas are slow growing, and if pregnancy occurs the growth will in all probability be checked, or at least retarded. If pregnancy does not occur, another operation can be done later, and a cure assured the patient by bilateral oophorectomy. In Case No. 9118, complaining of sterility, a conservative operation was performed, although both ovaries contained ovarian hematomata. The ovaries were densely adherent deep in the pelvis and the uterus in retroversion. This patient became pregnant five months after the operation.

Five supravaginal hysterectomies with bilateral salpingo-oophorectomy were performed in nine cases before the present knowledge of these cysts. In the four other cases, the uterus and ovarian tissue were left behind, an oophorectomy, or a resection of the ovary, was done. One of the cases in which evidently some of the healthy part of the cystic ovary was transplanted into the uterine cornua, now, after 14 months, has "adhesions" about the left ovary and posterior wall of the uterus. The condition is not considered serious enough to warrant reoperation. The other cases have not been heard from.

The prognosis in the radical operative pro-

cedure is excellent, for with the removal of the ovaries the growth stops. In the conservative procedures we believe the prognosis to be good also. If the patient becomes pregnant the prognosis is very good, and if not, it is questionable whether the small amount of endometrial-like tissue left will grow fast enough to cause symptoms.

In every case there were adhesions present, including in all the sigmoid, rectum, round ligaments, posterior wall of the uterus, posterior surface of the broad ligaments. In each case the ovary was adherent. The disease was bilateral three times; on the right side eight times; on the left, five. All of the ovarian cysts contained dark, chocolate, tarry fluid.

The histories, physical findings, operative findings, descriptions of the specimen, early pathological report, and later pathological report will be found in the 16 case reports that follow. In all these case reports supravaginal hysterectomy includes bilateral salpingo-oophorectomy, which is performed as part of the routine in hysterectomies at the Free Hospital for Women.

In nearly every case the diagnosis of endometrial hematoma of the ovary was confirmed by Dr. Frank B. Mallory, pathologist to the Boston City Hospital.

February 26, 1909, No. 2017, Mrs. M. K., age, 41; children, none; miscarriages, none. Menstruation, which began when the patient was twelve, was regular until the past two years. Since then it has occurred every two to three weeks, and there was no period in January. Later a long walk and hot bath resulted in a severe attack of flowing with the passage of clots, which necessitated rest in bed.

Examination, February 28, 1909: Uterus retroflexed and drawn back in pelvis. Indefinite, not very tender mass felt behind uterus.

Operation, March 4, 1909, by Dr. W. P. Graves. Supravaginal hysterectomy. Median incision. Pelvic structures bound by adhesions which were freed with finger. Hematoma of the right ovary ruptured. Adhesions between sigmoid and left round ligament freed. Both ovaries and tubes so involved that they were removed with the uterus. Sigmoid covered with adhesions in the cul-de-sac. Discharge examination, March 23, 1909: Negative.

PATHOLOGICAL REPORT.

Macroscopical Examination: Specimen consists of uterus with tubes and ovaries attached, vermiform appendix, and a small myoma. There are adhesions about the fundus especially in the posterior surface and about the tubes and ovaries. Both ovaries are much enlarged and cystic. Embriated ends of both tubes are closed. On opening the uterus the walls seem slightly hypertrophied. The endometrium is

about 2 mm. in depth, but there are no intrauterine growths or polypi. Both tubes and ovaries are densely adherent and bound into one mass. The left tube is dilated and contains clear straw-colored fluid. Its walls are thick, forming a true hydrosalpinx.

Microscopical Examination: Fundus shows normal wall with marked hypertrophy of the endometrium. Tube is much dilated with flattened and atrophied villi and rather thin muscular walls. Ovary shows chronic fibrous thickening and several cystic follicles. The other ovary shows the same condition.

Pathological Diagnosis: Hypertrophy of endometrium; bilateral cystic oöphoritis; hydrosalpinx.

The pelvic examination and operative findings in this case are typical, and the gross specimens suggestive. The microscopic slides show endometrial-like tissue in both ovaries. In one there are a few glands and much columnar epithelium upon vascular walls. Hemorrhage is both fresh and old. Another slide shows an area of endometrial-like tissue with cyst wall in connection. The endometrial-like tissue is perfect, and by far the best specimen we have seen. This piece of endometrial-like tissue measures 2.5 cm. x 2 cm. and contains many small tubular glands surrounded by stroma. Without study of the whole section, the endometrial-like tissue closely resembles a section from the uterine mucosa.

April 14, 1913, No. 4136, Mrs. B. W., age, 48; children, five; miscarriages, none. For the past year the patient has "felt womb coming outside," and has had a dragging down feeling with sacral backache. The menopause occurred nine months ago. There had previously been five normal labors.

Examination, April 14, 1913, showed separation of the recti muscles; atrophy of the external genitals; cystocele; lacerated cervix and perineum, with some prolapse of uterus.

Operation, April 16, 1913, by Dr. W. P. Graves. Dilatation and curettage; trachelorrhaphy; anterior colporrhaphy; perineorrhaphy; supravaginal hysterectomy. Median suprapubic incision made. Adhesions found on back of the uterus and low down in the pelvis. The latter were separated. Tubes and ovaries normal. Discharge examination, June 6, 1913: Negative.

PATHOLOGICAL REPORT.

Microscopical Examination: Specimen consists of a uterus, with both tubes and both ovaries, and a piece of cervical tissue. Uterus is a supravaginal hysterectomy and measures 5 cm. x 6 cm. No adhesions seen. Right tube is 5½ cm. long, very tortuous, and shows no adhesions. Right ovary is 2½ cm. x 1 cm. It shows nothing remarkable. Left tube is 5 cm. long. Left ovary measures 3 cm. x 2 cm. It

has many adhesions on it and contains a few cysts.

Microscopical Report: One ovary shows a good deal of connective tissue in the outer layer of the cortex. The other ovary shows the same.

Pathological Diagnosis: Interval endometrium; chronic bilateral salpingitis; normal ovary; periovaritis; chronic cervicitis.

This is not a typical history because the patient had passed the menopause. The pelvic examination and the gross specimens are not suggestive. On the surface of the ovary is a piece of endometrial-like tissue 0.5 mm. x 1 mm. in diameter that is very suggestive of uterine endometrium. No cyst was found in connection with this tissue. The ovary is atrophied and the endometrial-like tissue does not appear to be active.

March 28, 1914, No. 4815, Mrs. G. C., age, 41; children, two; miscarriages, none. Patient has had backache and a dull ache in both lower quadrants for the last year. These are worse during menses which, for the past year, have been very irregular, with profuse bleeding, lasting six days to three weeks. There were two normal, full term pregnancies. Previous operations: Posterior gastro-enterostomy nine years ago.

Examination, March 30, 1914, showed large, anteverted uterus, with some lack of mobility; scar in posterior vaginal wall; lacerated cervix and perineum; cervical polyp.

Operation, March 31, 1914, by Dr. F. A. Pemberton. Excision of cervical polyp; dilatation; perineorrhaphy; coeliotomy; supravaginal hysterectomy. Uterus was forward. Adhesions about the adnexa on both sides were separated. Discharge examination, April 13, 1914, was negative.

PATHOLOGICAL REPORT.

Macroscopical Examination: Specimen consists of a cervical polyp, curettings and a uterus with both tubes and ovaries. Uterus shows a supravaginal hysterectomy, and measures 6 cm. x 5 cm. Endometrium is 3 mm. thick, and smooth. There are no adhesions. Tubes and ovaries look normal. On section right ovary is found to consist of a cyst 3 cm. in diameter. There is no ovarian tissue left. Left ovary is small and seems to be atrophied. Sections taken of polyp, curettings, uterine wall, right tube, and left ovary.

Microscopic Examination: Left ovary shows in one place glandular tissue surrounded by connective tissue which looks like endometrium of the uterus. **Diagnosis:** Interval endometrium; gland hypertrophy; mucous polyp of the cervix; chronic salpingitis (bilateral); atrophy of left ovary; adenomyoma; retention cyst of right ovary.

This history and pelvic examination are not typical, nor is the gross specimen typical. Near

the surface of the left ovary is found a cyst about 1 mm. in diameter and about it a layer of definite, endometrial-like tissue with a good stroma, possibly connecting with a larger cyst. This fact could not be determined as the gross specimen was not available.

June 19, 1919, No. 8496, Mrs. B. F., age, 43; married seventeen years; children, none; miscarriages, none. In February the patient went to bed complaining of severe pain in the left side. Since then after each period she has had pain in abdomen and back lasting about a week. Menstruation regular; flows three days; always some pain.

Examination, June 19, 1919, found uterus in retroflexion, and a cyst of the left ovary the size of an apple.

Operation, June 21, 1919, by Dr. W. P. Graves. Supravaginal hysterectomy. Very adherent mass felt in the left side involving the rectum. Right tube and ovary normal. Intramural fibroid in the uterus. The mass, evidently a blood cyst of the ovary, was delivered with great difficulty on account of dense adhesions and cellulitis involving the peritoneum and extending to the rectum. Thickened nodules felt in the rectum were not touched. Left broad ligament badly mutilated in removing the mass because of the density of the adhesions.

Examination, November 1, 1919: Patient in excellent condition. Some induration in the left broad ligament, probably old hematoma.

August 3, 1921. Patient is well except that on two occasions she has had flow similar to menstruation. Examination shows pinkish discharge. There is a mass, the size of a lime and not tender, in the left side of the pelvis similar to that felt one month after operation. There is a question of a cyst of the remaining ovarian tissue, or of an adenomyoma following a chocolate cyst.

October 10, 1921. Patient feels fine. No return of bleeding. Examination shows the pelvis entirely clear with no sign of previous swelling.

PATHOLOGICAL REPORT.

Microscopical Examination: Specimen consists of a uterus with both tubes and ovaries. Uterus is 6 cm. x 5 cm. x 3 cm. Endometrium is 3 mm. thick. There are three small, intramural fibroids. One ovary is normal. Part of other ovary shows a few adhesions on the outside and a collapsed cyst. Sections taken of the uterine wall, both tubes and ovaries.

Microscopical Examination: One ovary shows the wall of a simple cyst with adhesions on the surface.

Diagnosis: Interval endometrium; gland hypertrophy; normal tubes; normal ovary; cystic degeneration of the ovary with perioophoritis; multiple fibroids.

The history and physical findings are typical. The operation revealed an endometrial

hematoma of the left ovary; a probable implantation in the left broad ligament; and a probable adeno-leiomyoma in the rectum. The gross specimens were not recognizable. A tumor of the left cornu of the uterus was sectioned. On re-examination these slides showed endometrial-like glands in small areas in the left ovary with characteristic stroma, much old blood, and an adeno-leiomyomata of the left uterine cornu.

The subsequent history shows a shrinking of the rectal tumors, and a bleeding possibly from a small remaining piece of endometrium or from an adeno-leiomyoma in the cervix, stimulated by small bits of ovary that could not be removed. In this case we believe Sampson's theory of implantation of adeno-leiomyomata is supported very well.

January 2, 1920, No. 8935, Mrs. F. W. F., age, 28; children, one; miscarriages, none. For some time the patient has had a backache and a sense of pressure against the rectum followed by a rather sharp attack of pain on November 22, 1919. Menstruation, regular; flows five days; last period December 13, 1919.

Examination showed very marked retroflexion and some prolapse of a large, congested uterus, which pressed on the rectum. There was a small protuberance on the back of the uterus, and a long, slightly torn, cystic cervix.

Operation, January 31, 1920, by Dr. W. P. Graves. Anterior colporrhaphy; perineorrhaphy; coeliotomy; right salpingo-oophorectomy; anterior fixation of round ligaments. Cystic mass in the posterior cul-de-sac felt much larger than at previous examination, and appeared to be adherent. Coeliotomy; Median incision. Uterus large, soft and retroverted. Adherent cyst of right ovary impacted in the pelvis. Adhesions released. Cyst found to be partly necrotic.

PATHOLOGICAL REPORT.

Microscopical Examination: Specimen consists of an ovarian cyst with tube attached, and appendix. Cyst measures 7 x 6 x 3.5 cm. and is filled with a chocolate colored material. Wall is thin and smooth on outer side; inner surface is studded with small papillary projections. Sections taken from tube, appendix, and cyst wall.

Microscopical Examination: Tube normal. Appendix normal. Cyst wall is that of a papillary serous cyst adenoma.

Diagnosis: Papillary serous cyst adenoma; normal tube; normal appendix.

Typical history coupled with a typical pelvic examination. The operative findings and the description of the gross specimens are typical except for the papillary projections. The new slides in this case show a cyst wall, lined with endometrial-like glands, in various shapes and sizes, and a definite stroma. There is both old

and new blood present. The ovary is active. In other sections a papillary serous cyst adenoma is shown. This is a very good specimen of endometrial hematoma of the ovary.

March 18, 1920, No. 9118, Mrs. C. Y., age, 25; married two years; children, none; miscarriages, none. Chief complaint: Sterility. Also has pains in the waist line and in the rectum. Has had diarrhoea on and off for a year. Menstruation: Irregular, and painful, before marriage.

Examination, March 18, 1920: Retroverted uterus, adherent to rectum.

Operation, April 29, 1920, by Dr. W. P. Graves. Dilatation; appendectomy; resection of both ovaries; anterior fixation of round ligaments. Ether examination: Uterus retroverted and adherent. Coeliotomy; both ovaries cystic and both adherent deep in pelvis. Cysts, broken in releasing the adhesions with escape of dark, bloody fluid, were probably corpus luteum cysts. Necrotic portions of the cysts trimmed off and wound closed.

June 11, 1920. Patient still complains of pain similar to that felt before operation in the left flank and back, but not as constant. Sept., 1920, patient pregnant.

PATHOLOGICAL REPORT.

Macroscopical Examination: Specimen consists of an appendix and ovarian tissue. Ovarian tissue shows wall of a cyst with smooth lining. Section taken.

Microscopical Examination: Ovarian cyst wall is lined with a single layer of low cells. Tissue beneath is full of fresh blood and blood pigment. The cells are of the shape that suggest lutein cells.

Diagnosis: Corpus luteum blood cyst; normal appendix.

The history and pelvic examination should at once suggest the presence of an endometrial hematoma of the ovary. The description of the operation further confirms its presence. The new slides made of the tissue show a layer of columnar epithelium resting upon a very thin vascular layer in which there is both old and new blood, this in turn resting upon fibrous tissue. This is a cyst wall and in places it is comparable to the wall of a hematoma in an adeno-leiomyoma.

December 16, 1920, No. 9414, Mrs. C. K., age, 36; children, two; miscarriages, none. Chief complaint: Bearing down sensation in the lower abdomen. Menstruation has been accompanied by marked dysmenorrhea with hemorrhages since April.

Examination, December 17, 1920: Relaxed vagina; rectocele; uterus in complete retroversion flexion, with a question of fibroid in the wall.

Operation, December 21, 1920, by Dr. W. P. Graves. Dilatation and curettage; anterior col-

porrhaphy; perineorrhaphy; supravaginal hysterectomy; coeliotomy. Uterus found to be retroverted and adherent.

Discharge Examination, January 2, 1921: Negative.

PATHOLOGICAL REPORT.

Macroscopical Examination: Specimen consists of a uterus with both tubes and ovaries attached. The tubes and ovaries are firmly adherent to the posterior wall of the uterus. Right tube and ovary form a mass 5 x 3 cm. The ends of the tubes are closed. Tube dilated and contains chocolate colored mucous. Ovary is normal in the gross. Left tube and ovary form a mass 5x3 cm. and this mass consists, as do the other adnexa, of a thin-walled and dilated tube containing chocolate colored material, with a normal appearing ovary that contains a corpus luteum cyst. Uterus is not remarkable except for adhesions.

Diagnosis: Gland hypertrophy of the endometrium; salpingitis isthmica nodosa; corpus luteum cyst (left); peri-oöphoritis (right); hemato salpinx (bilateral); normal appendix.

Increasing dysmenorrhea and irregular flowing with menorrhagia, together with the pelvic examination are typical. The operative findings without the description of the adnexa are not typical. The tubes seem to be the part involved in the description of the gross, but microscopically the ovaries are also involved. The salpingitis isthmica nodosa on recutting shows an adeno-leiomyoma of the left cornu. The new slides show a hemato salpinx (bilateral) with glands in the wall of the tube. The left ovary shows a corpus luteum cyst. In the ovary there is an area of endometrial-like tissue with stroma.

December 27, 1920, No. 9432, Mrs. M. B. H., age, 26; married two and one-half years; children, none; miscarriages, none. For two years, every two or three weeks, the patient has had a dull, bearing down pain in the left lower quadrant, lasting twelve hours. This pain does not accompany catamenia, and never occurs in the right side. Patient is anxious for children. Menstruation began at fifteen and has been regular every six weeks. Previous operations: Appendectomy six years ago.

Examination, December 23, 1920: Deep abdominal sear; uterus retroverted; adhesions about left ovary.

Operation, December 28, 1920, by Dr. W. P. Graves. Dilatation of the cervix; excision of ovarian cysts; implantation of ovarian tissue; anterior fixation of the round ligaments; bilateral oöphorectomy; coeliotomy; bilateral hydrosalpinx; bilateral salpingitis isthmica nodosa. Both tubes and ovaries adherent. Right ovary contained a fairly large corpus luteum cyst which was ruptured in freeing the ovary, with the escape of a large amount of thick black

fluid. Resection of both ovaries. Implantation of ovarian tissue. Sections of left ovary previously removed placed in each cornu of the uterus.

Discharge Examination, January 10, 1921: Wound healed; uterus in good position; some induration on the left.

Examination, February 24, 1921: Adhesions around left ovary to posterior wall of the uterus.

PATHOLOGICAL REPORT.

Microscopical Examination: Specimen consists of parts of both ovaries and both tubes. Fimbriated end of tube is attached to the ovary. Wall of tube is thickened near uterine end. One piece of ovary consists chiefly of a cyst filled with dark brownish coagulum. Lining of the cyst wall is smooth. Other ovary contains many small cysts filled with clear fluid. Sections taken of both ovaries and tubes.

Microscopical Examination: One ovary shows the wall of a follicular retention cyst. Other ovary shows adhesions and small cysts.

Diagnosis: Peri-oöphoritis; follicular retention cyst; sub-acute salpingitis.

This is not a typical history, but it is suggestive when considered with the pelvic examination. The operative findings show involvement of all pelvic structures. The description of the right ovary helps confirm the diagnosis. The sections of the tubes show a bilateral hydrosalpinx. A slide of the right ovary shows it to be active with an area of endometrial-like tissue near the surface, composed of a few glands and tissue typical of endometrial stroma, containing new and old blood. The corpus luteum described in the operative findings was not found microscopically.

January 10, 1921, No. 9460, Mrs. S. M., age, 30; married eleven years; children none; miscarriages, none. In December menstruation started normally but has kept on constantly since. The flow varies very much in severity. No clots or pain. Otherwise patient feels well.

Examination, January 6, 1921: Mass attached to right horn of uterus pressing it forward was thought to be a fibroid.

Operation, January 11, 1921, by Dr. W. P. Graves. Supravaginal hysterectomy; coeliotomy; bilateral hydrosalpinx. Tubes were adherent in the posterior cul-de-sac. Fibroid found in the posterior wall of the uterus near internal os. Tubes freed from adhesions.

Discharge Examination, January 20, 1921: Negative.

PATHOLOGICAL REPORT.

Microscopical Examination: Specimen consists of a fibroid uterus with both tubes and ovaries attached. Uterus is covered with firm, fibrous adhesions. There are three intramural

fibroids. Both tubes are greatly distended and filled with clear fluid. Left ovary is filled with a dark brown coagulum. Right ovary is filled with clear fluid.

Microscopical Examination: Endometrium is of the interval type.

Pathological Diagnosis: Interval endometrium; hydrosalpinx (bilateral); cystic degeneration of the ovaries; multiple fibroids; obliterated appendix.

Operative findings and pelvic examination are not typical. The left ovary shows a cyst wall with an irregular, wavy layer of columnar epithelium resting on a definite stroma with both new and old blood in it. The cyst cavity is full of old blood.

October 11, 1921, No. 9891, Mrs. H. F., age, 24. Last winter patient had a "dropping feeling" in pelvis. On July 4th had severe pains in the lower abdomen which have continued off and on until the present time. This pain is worse during menstruation, which is regular. Previous operation: Appendectomy.

Examination, October 11, 1921. Chronic pelvic inflammation. Tender mass in posterior cul-de-sac.

Operation, October 25, 1921, by Dr. W. P. Graves. Left oöphorectomy; anterior fixation of round ligaments; coeliotomy. Uterus in the first degree of retroversion. Right tube and ovary normal. Left tube normal. Left ovary cystic and adherent to the posterior wall of the uterus and broad ligament. When the cyst was released it was found to be a chocolate cyst.

PATHOLOGICAL REPORT.

Macroscopical Examination: Specimen consists of an ovary which measures 4 cm. x 5 cm. x 3 cm. Ovary presents a cyst that is filled with chocolate-colored material. Cyst is multilocular. Larger cyst appears to have been ruptured at some previous time and is now covered with adhesions. Sections taken from the cyst wall and from adhesions.

Microscopical Examination: Sections show the wall of a corpus luteum cyst. This was thought to be a perforating hemorrhagic cyst (Sampson's Cyst), but it could not be proved microscopically. Adhesions show no sign of endometrial-like tissue.

Pathological Diagnosis: Corpus luteum cyst.

Pain in the lower abdomen and a tender mass in the posterior cul-de-sac are typical, except for the possibility of salpingitis. The operative findings are typical and the diagnosis was made at operation. The macroscopic findings did not show the endometrial-like tissue which completely lined one of the smaller cysts until 15 or 16 slides had been made. No glands were found but a thin stroma under a layer of columnar epithelium was present.

Old and new blood was found in the stroma.

November 17, 1921, No. 9933, Mrs. J. C., age, 32; children, one; miscarriages, none. Patient complains of pain across lower abdomen which is worse during catamenia. Menstruation began when she was fifteen and has been regular.

Examination, October 3, 1921: Right kidney palpable; retroversion with moderate flexion of uterus; relaxation of vagina; question of prolapse of ovaries; question of adhesions.

Operation, November 22, 1921, by Dr. J. V. Meigs. Dilatation and curettage; trachelorrhaphy; perineorrhaphy; left oöphorectomy; appendectomy; anterior fixation of round ligaments. Adhesions in the pelvis and on posterior wall of uterus; left ovary adherent to posterior surface of the broad ligament. These adhesions were broken up. Left ovary was found to have a small perforation in its posterior surface, suggesting a possible hemorrhagic cyst that contains endometrium. There were no bluish areas on the broad ligament or on the posterior wall of the uterus.

Discharge Examination, December 8, 1921: Negative.

PATHOLOGICAL REPORT.

Macroscopical Examination: Specimen consists of an ovary which has a perforation on its lateral wall. There are two smaller areas on posterior surface with a small amount of dark bloody material coming from them. On section the ovary is found to contain a cyst filled with dark brown material. Cyst measures 1 cm. in diameter. Section taken through the whole ovary to show the area about the perforation.

Microscopical Examination: Section from the ovary shows a cyst lined with endometrial epithelium with evidences of old blood in its walls. There is blood pigment in many endothelial leucocytes. About the perforation there are glands resembling endometrial glands with a small but definite amount of stroma about them. In some areas in the cyst there is an absence of epithelium and here the cyst wall consists of a fibrous tissue. At the distal portion of the ovary there are areas still more strongly suggestive of endometrium and its stroma. These areas do not seem to be connected in any way with the cyst. Diagnosis: Interval endometrium; chronic cervicitis; normal appendix; perforating hemorrhagic cyst of the ovary containing endometrium (Sampson's Cyst).

The history and pelvic examination are quite typical. At operation the diagnosis was made. No implants in the peritoneum were found. Section was made through the whole ovary to show the perforation. Gland inclusions in the slides were found very close to the endometrial tissue. Is it possible that the etiology of these cysts is as follows: Germinal epithelium, gland

cleft, gland inclusions, and lastly endometrial-like tissue? Occasionally, sections are very suggestive of it.

November 15, 1921, No. 9943, Mrs. K. MacL., age, 42; children, none; miscarriages, none. Since August the patient has noticed an abdominal tumor steadily increasing in size. Menstruation: Normal.

Examination, November 17, 1921: Abdominal tumor; question of a cyst of the ovary, or a fibroid; small vagina.

Operation, November 30, 1921, by Dr. W. P. Graves. Supravaginal hysterectomy; coeliotomy. A large, necrotic cyst of the left ovary was freed from adhesions and removed. The adhesions included rectum which was badly involved, but not blocked. Condition thought to be malignant. Cyst broken while being removed and abdomen flooded with fluid. Small chocolate cyst of the right ovary removed with uterus and the cyst. Seed metastases seen on the left broad ligament. Discharge Examination, December 15, 1921: Negative. Deep x-ray treatments advised.

Examination, January 26, 1922: Cervix well held up. Patient in good condition.

PATHOLOGICAL REPORT.

Macroscopical Examination: Specimen consists of a uterus with one tube and ovary attached and one tube and ovary separate. Separate ovary presents a collapsed cyst 15 cm. x 9 cm. x 9 cm. with a thick red wall. On the inside of the cyst is a friable mass measuring 5 cm. in its greatest diameter. The other tube and ovary form a mass 6 x 4 x 3 cm. The ovary contains a cyst. Tube is normal. Uterus is normal in size, but there is a small fibroid in its wall.

Microscopical Examination: One ovary shows the wall of a corpus luteum cyst and the other a malignant papillary cyst adenoma.

Pathological Diagnosis: Interval endometrium; endometrial polyp; normal tubes; corpus luteum cyst; malignant papillary cyst adenoma; leiomyoma.

History and pelvic examination are not typical. A malignant tumor of the left ovary and a small "chocolate cyst" of the right ovary were removed. No mention is made of the "chocolate cyst" in the gross description. This right ovary contains a collapsed cyst with a perforation on the surface. This cyst is lined with columnar epithelium, and has a vascular stroma which contains old and new blood. It is a very good example of endometrial hematoma in the ovary.

December 27, 1921, No. 9986, Mrs. A. E. P., age, 51; married twenty-one years; children, none; miscarriages; question of one. Patient complains of a bearing down sensation and pain in both sides. The abdomen feels heavy. Menstruation: Irregular; flows every three to six months.

Examination, December 27, 1921, showed tumor, probably fibroid of the uterus, and a small tumor in the vagina.

Operation, December 29, 1921, by Dr. F. A. Pemberton. Excision of fibroma from vagina; supravaginal hysterectomy; appendectomy; coeliotomy. Large fibroid found growing from the left cornu of the uterus. Right tube and ovary densely adherent in the right side of the posterior cul-de-sac. Discharge Examination, January 16, 1922: Negative.

PATHOLOGICAL REPORT.

Macroscopical Examination: Specimen consists of a uterus with both tubes and ovaries; also a small tumor of the vagina and appendix. Uterus contains multiple leiomyomata and measures 14 x 14 x 13 cm. Left tube and ovary appear to be normal. Right tube and ovary have a few adhesions to their surface. Ovary is cystic and contains bloody fluid.

Microscopical Report: Tube shows chronic salpingitis. Ovary is normal except for a few strands of connective tissue attached to the surface. The tumor from the vagina shows a fibroma.

Pathological Diagnosis: Gland hypertrophy of the endometrium; endometrial polyp; peri-oöphoritis; chronic salpingitis; multiple leiomyomata; fibroma from vagina; normal appendix.

There is no suggestion of this entity in either the history or pelvic examination. At operation the cyst, tube and ovary were very adherent and full of old blood. The possibility of endometrial hematoma was discussed at the operation but the age of patient ruled it out. The right ovary showed upon re-examination after cutting many sections, very definite endometrial tissue, stroma, and old blood. In the section is an early hematoma partly lined with endometrial-like epithelium with many gland inclusions about it.

January 9, 1922, No. 10014, Mrs. R. C., age, 36; married fourteen years; children, none; miscarriages, none. Patient complains of pains in back and right side of two-weeks' duration. A mass has been present in the right side of the abdomen for two years. Previous operations: cholecystectomy, 1903; appendectomy, 1904; lysis of adhesions, 1907; oöphorectomy, 1911; dilatation and curettage for retroversion, 1914; intestinal obstruction.

Examination, January 9, 1922, showed uterus in good position.

Operation, January 12, 1912, by Dr. Harold Baker. Dilatation and curettage; right oöphorectomy; cauterization of the cervix; repair of post-operative hernia; coeliotomy; large hernial sac opened. The pelvis was filled with dense adhesions. Right ovary was cystic and about the size of an orange. With considerable dif-

ficulty this cyst was dissected free from the other pelvic organs, which were all adherent.

Discharge Examination, February 2, 1922: Negative.

PATHOLOGICAL REPORT.

Macroscopical Examination: Specimen consists of a cyst of the ovary measuring 10 x 9 cm. Cyst is multilocular and contains dark brown fluid. It is covered with adhesions.

Microscopical Examination: This section shows the wall of a hemorrhagic cyst of the ovary. There is blood in the cyst and fresh and old blood in the cyst wall. The old blood is in the form of blood pigment and is being taken up by endothelial leucocytes. In one area there are numerous glands similar to uterine glands and surrounding these glands is a stroma similar to the stroma about the glands of the endometrium.

Pathological Diagnosis: Hemorrhagic cyst of the ovary containing endometrial tissue (Sampson's Cyst).

In this case the history, examination, and operative findings are all obscured by the many operations which the patient has had. The cyst the size of an orange was multilocular and very adherent, and full of dark brown fluid. The wall contained a few glands and stroma very much like endometrium. It is very probable that some of the previous operations were done for the same process which was unrecognized at the time. This case probably bears out Sampson's findings concerning peritoneal implants.

January 3, 1922, No. 10041, Mrs. E. S., age 55; children, none; miscarriages, none. Catamenia ceased three years ago, and the patient was well until two months ago when she noticed a little, slightly-colored, non-odorous, watery discharge. There was no bright bleeding, and the patient feels perfectly well.

Examination showed an unruptured hymen, and a small, atrophied uterus.

Operation, January 7, 1922, by Dr. W. P. Graves. Ether examination: Uterus could not be felt and probably always had been infantile. Dilatation and curettage. Cervix dilated easily. Depth of uterus normal. Large amount of curettings obtained that were not characteristic.

Pathological Report: Adeno-carcinoma of the fundus uteri.

Operation, January 20, 1922, by Dr. W. P. Graves. Supravaginal hysterectomy and with coming out cervix. Coeliotomy. Long median incision made. Adhesions found in the posterior cul-de-sac. Right ovary cystic. In releasing adhesions the cyst was ruptured letting out a moderate amount of dense, black material. This was evidently a chocolate cyst.

PATHOLOGICAL REPORT.

Macroscopical Examination: Specimen consists of a uterus with both tubes and ovaries attached. In the right cornu of the uterus is an irregular growth, soft and friable. Left tube and ovary normal. Right tube normal. Right ovary measures $3\frac{1}{2}$ x $2\frac{1}{2}$ cm. and contains on posterior wall a perforation from which chocolate-colored material is oozing. On section presents a cyst measuring 3 cm. in diameter that appears to be an endometrial hematoma.

Microscopical Examination: Adeno-carcinoma of the fundus. The ovarian cyst wall shows a layer of fibrous tissue and loose cellular tissue with old blood pigment in endothelial leucocytes. There are a few traces of columnar epithelium lining cyst. Probably an atrophied endometrial hematoma.

History and pelvic examination are not typical, but the operative findings are suggestive. The cyst, and its contents, are typical. The microscopic slides show a thick fibrous layer full of old blood in pigment form in endothelial leucocytes. There is some columnar epithelium present which has been stripped from the wall. The cyst wall in this case is typical and with the small amount of epithelium present it has the appearance of an atrophying endometrial hematoma.

April 7, 1921, No. 10174, Mrs. W. A. McC., age 24, children, none; miscarriages, none. Has always had painful menstruation.

Examination April 7, 1921. Uterus in marked retroversion-flexion and apparently adherent.

March 6, 1922. Has had two severe attacks of pain, one Feb. 22 and one today.

Examination March 6, 1922. Tenderness in the lower abdomen especially on the right. There is a mass on the right which is tender. Temperature is 99.4

Operation March 14, 1922, by Dr. W. P. Graves. Right oophorectomy, appendectomy, myomectomy, anterior fixation of the round ligaments. Median incision. Chocolate cyst on the right, size of a small orange, adherent. Cyst ruptured when released. Ovary removed. Right tube, left ovary, and tube normal in appearance. The appendix had a short mesentery and was attached in the pelvis. Its tip was attached to the posterior wall and to the right broad ligament. Small myoma removed.

PATHOLOGICAL REPORT.

Macroscopical Examination: Specimen consists of a cyst of the ovary, 5 cm. in diameter, full of chocolate-colored material. Walls of the cyst are thick, there is a perforation 2 cm. in diameter on the posterior wall of the ovary. The cyst shows no adhesions except at the point of contact. Appendix is 8 cm. long and has ad-

hesions at its tip. There is a small tumor from the uterus 1 cm. in diameter.

Microscopical Examination: The wall of the ovarian cyst shows some active ovarian tissue and a cyst lining of columnar epithelium which runs above a very narrow strip of cellular tissue containing blood. In one area deep in the wall is a gland of endometrial type. Another section shows columnar epithelium resting upon tissue which suggests endometrial stroma and contains both old and new blood. The appendix is obliterated at the tip. In one area in the outer part of the wall there are two glands surrounded by a definite stroma that contains extravasated blood. This tissue resembles endometrium. Another section of the appendix shows a gland deep in the wall with stroma about it. The small tumor is a leiomyoma with two endometrial-like glands in its substance.

Pathological Diagnosis: Endometrial hematoma of the ovary; obliterated appendix with probable adeno-leiomyoma in its wall. Adeno-leiomyoma of the posterior wall of the uterus.

198 Commonwealth Avenue.

THE SOCIAL HISTORY IN RELATION TO HEART PATIENTS.

By WILLIAM D. REID, M.D., BOSTON.

[From the Heart Clinic of the Boston Dispensary.]

In out-patient hospital work one is frequently impressed with the importance of the patient's history as collected by the Social Service Department. The value of such data and the assistance of the social workers has become increasingly evident to me since taking charge of an out-patient clinic for heart patients at the Boston Dispensary. It is common to find that the failure to obtain the expected degree of success in treatment is readily explainable after investigating the patient's home or business surroundings; in other instances the good result achieved would not have occurred without the assistance of the social worker assigned to the case.

The remarks apply with equal force to the work of the general practitioner. He usually does not have the assistance of a Social Service Department, but must himself be both physician and social worker. The experienced physi-

cian instinctively notes the environment of his patient and does not limit this attention to the strictly medical aspects of the case. The opportunity for this is, of course, more readily afforded when the patient is visited in his home, but at times the information is obtained only as a result of direct search similar to that employed in making the medical diagnosis. It is with the hope of emphasizing an important side of the treatment of heart patients that this paper is offered.

Perhaps this object can be most readily accomplished by citing a few case reports. The medical histories will be much abbreviated, while the social histories will be given somewhat more fully, conforming as nearly as possible to the words used by the social worker.

CASE 1. Boston Dispensary, No. 182829. Mary P., married, 42 years of age.

Past History. Good; no history of disease of etiological importance as regards the heart.

Present Illness. Symptoms 1½ years. Smothering sensation, dyspnea on exertion, weakness in the legs when walking.

Physical Examination. Cardiac impulse in the fifth space at anterior axillary line. At apex there is a rough systolic murmur masking the first sound, and a diminuendo diastolic murmur following the second sound. Heart rate 64, with frequent irregularities which disappear when the rate is accelerated by exercise.

Diagnosis. Rheumatic heart disease, premature beats, mitral stenosis and regurgitation.

Under observation for one year. Can exert but little. Heart rate 64 to 78; premature beats present at times.

Social History. Aged 42 years, born in Newfoundland, married and mother of six children, eldest 17 years, and youngest 6 years.

Mr. P., age 43, a laborer, with regular work. A man of quiet, even temper, with little to say in running the house. The children were husky and lively, showing affection for the mother.

The family lived in a single house of six rooms; two rooms on a floor, with toilet in the basement. This arrangement necessitated considerable stair climbing. The home was comfortably furnished. The rent \$16 per month; income of family \$40 per week.

Mrs. P. was a good housekeeper, strenuous and irritable, performing all the work in the home, including the washing and the bringing up of the coal from the cellar. She had no recreation. The day's work began at 5:30, when breakfast was prepared for her husband and son and two lunches taken to work, a second breakfast for the other children; a hearty noon meal and dinner at night. Besides the usual routine of her housework, she did much of the sewing for the family. She possessed a sewing machine.

After Mrs. P.'s second visit to the Heart Clinic, where she had received instructions in regulating her life, she asked the social service worker to call at her home and impress on Mr. P. the seriousness of her condition and the necessity for relief from housework. The visitor called and found the family at home. Mr. P. seemed interested after being told what the doctor had outlined for his wife's care. He looked much relieved, saying he was glad to know what ailed her because after each visit to the Dispensary she returned home as though she had a grudge against the family; why, he did not know. He agreed to relieve her and to make the children do the same.

The result of home supervision was as follows: The washing was sent out. The children brought the coal, did the sweeping and dishes, etc. An army cot was purchased and placed in the room leading from the kitchen where Mrs. P. could rest at intervals. Later, the family moved into a five-room flat to avoid stairs. While there have been relapses in the family's good intentions, a better understanding of Mrs. P.'s needs and moods has been established.

Comment. At first this patient did not seem to be getting along as well as was expected. The reason was obvious after the visit of the social worker, and benefit was then soon apparent.

The above case illustrates the importance of having the family understand the patient's condition. In many instances this should not be left to the patient.

CASE 2. Boston Dispensary, No. 196666. Mary H., 23 years, married. Sent in by district nurse for cardiac examination.

Past History. Rheumatism at eight; tonsillitis once. Last baby is two years old.

Present Illness. Dyspnea for five minutes on climbing one flight of stairs. Cough rare, tires easily, does all housework (scrubbing, etc.).

Physical Examination. Fairly well developed and poorly nourished. Slight cyanosis of lips and finger tips, latter cool. Heart: Impulse maximum in fifth space one finger's breadth outside left midclavicular line. Border of deep cardiac dullness, second to fifth space; convex to left. Pulmonic second sound accentuated. Systolic murmur with first sound at apex, very loud second sound, and a faint third heart sound followed by a diastolic roll diminishing and crescendo.

Diagnosis. Rheumatic heart disease, heart failure, mitral stenosis and regurgitation.

Social History. Referred by Heart Clinic, which wishes patient to have rest from housework. Advice has also been given that patient have teeth repaired and tonsillectomy, but Mrs. H. is not inclined to follow this counsel.

Report from Family Welfare Society. This Society has had dealing with Mr. H.'s parents over a number of years, and lately with the H.'s themselves. Both families have been very unsatisfactory. Mr. H.'s father has tuberculosis and should be at Mattapan, but has come home, and now is sleeping with his eldest grandchild. The grandmother was convicted in court as a common drunkard; Mr. H. deserted repeatedly. Mr. H. is not a rugged man, but is well as far as is known. He is very lazy; has been employed off and on by a furniture mover, who says he only calls on him when he can get no one else, and then has to send a man over to drag him out of bed to work. Mrs. H. was taken from her parents as a neglected child, and brought up in the Home for Destitute Catholic Children. She has only recently found her father again. He lives in the tenement over the H.'s. Mrs. H. appears to be afraid of her husband and will do nothing contrary to his wishes. She is probably hungry, and there is no doubt that she and the children need help, but no private society will aid, as Mr. H. refuses to work in the woodyard and apparently cannot get work elsewhere. The priest has been seen and declines to aid; he aided last year but will not again.

On reporting these facts to the Heart Clinic, the advice was given that we explain the wife's condition to the husband and appeal to him on the purely selfish grounds of the danger of losing his wife or having her as an invalid on his hands if he did not see to it that she followed the physician's advice. The family was referred to the Society for the Prevention of Cruelty to Children and the Family Welfare Society on the ground that the children were neglected.

Worker called on family, which lived on first floor of a very poor tenement, from which it was about to be evicted. Patient could only say that she felt worse since visiting the Boston Dispensary, because the doctor scared her by telling her that she had heart disease and because she was afraid the children were to be taken from her. Worker explained what the Heart Clinic had said to husband, telling him that she should do nothing that required exertion; should not wash floors, windows or clothes; should not lift the children, etc. Husband replied that for the past month, since he knew she had heart trouble, he had not allowed her to do any of these things, but had done them himself. Mrs. H. does not deny this statement. Worker suggests convalescent home, but Mrs. H. is unwilling to leave the children.

Comment. There is more to this social history, but enough has been given to show the unfavorable environment of the patient, and the lack of cooperation on the part of the latter. Without a decided change in both of these,

no great improvement in the medical condition is to be expected.

CASE 3. Boston Dispensary, No. 192738. Rose S., 32 years, married. Referred with the diagnosis: "Myocarditis."

Past History. Influenza three years ago. Attacks similar to the present, when in high school eleven years ago, and three years ago when first baby was born.

Present Illness. Palpitation, with faintness, during the past two years. The duration is about ten minutes, and the cessation is gradual. Sometimes has the sensation as if the heart turned over. One flight of stairs causes no shortness of breath if taken at an ordinary pace. Occasionally has pains, mostly occurring at the time of the menses. The attacks or symptoms are usually associated with nervous causes or excitement. Feels she has had much trouble and reason to be nervous.

Physical Examination. Fairly well developed and somewhat thin (weight 107 pounds). Heart: Impulse palpable in fifth space in left midclavicular line; no enlargement to percussion. At the apex there is a faint systolic murmur with the first sound; no diastolic murmur appreciated. Pulmonic second sound is louder than aortic second but is not accentuated. Considerable respiratory arrhythmia; heart rate about 82.

Opinion. "No evidence of true heart disease. Proper term probably 'irritable heart' (i.e., normal heart in a nervous person). Environmental troubles could cause all these symptoms."

Social History. Children: Frederick, 11½ years; Eleanor, 8¾, and Pearl, 2½. Both little girls appear lovable and fairly healthy; normal births. Birth of boy was normal, but mother was under quite a nervous strain during pregnancy. Husband's peculiarities developed shortly after she was married; was abusive to her during the first pregnancy. He continued this abuse through ensuing years, and showed terrific temper, especially toward the boy, whom he frequently struck. Husband was committed to Psychopathic Hospital in 1916, sent to Westboro, and discharged in 1917. He came home and resumed his abuse toward his wife and son. Mother tried to have him arrested two or three times but changed her mind. The boy became cowardly, depressed, and prematurely old, while the mother became very nervous and easily upset.

In July, 1920, a visitor from the Boston Children's Aid Society went to the home and found the mother ill on a couch from the effects of the husband's brutality. She said he had knocked her down, kicked and stepped on her with heavy shoes, causing severe bruises, — glasses were broken and she was unable to get about. The husband was arrested and sent to the Cambridge jail, where he was bailed out by

his employer. He was later found guilty and placed on probation. In December, 1920, the court case was placed on file. In spite of the fact that the agent recommended probation, the officer was inclined to sympathize with the father as against the mother.

The patient has been examined by Dr. D. (an outside physician), who stated that she is a delicate, nervous woman, hypochondriacal and anæmic. He had treated her principally for pelvic irritation, due to the fact that she had not received proper care after the birth of her child.

Pearl was placed at board in a foster home by the Children's Aid Society, on December 22, 1920. Frederick, after being placed at board, developed many peculiarities which were felt to be abnormal. He was examined at the Psychopathic Hospital, and finally admitted to the School for Feeble-minded at Waverley, November 8, 1921.

Our contact with the patient has been one of fairly good cooperation, but we have felt that she never had a proper environment in which to get well. Mr. S. was arrested again in September, 1921, was found guilty of non-support of his wife and children and of being armed with a dangerous weapon. He was given eight months' sentence and was committed to the House of Correction. On November 1, 1921, the patient was operated on for complete hysterectomy and has gotten along well, but is worried about the approaching return of her husband from jail.

Comment. When this patient was referred to the Social Service Department it was hardly expected that such a chapter of trouble would be disclosed. Can it be wondered that the patient was upset nervously? It would seem that the diagnosis obtains much support.

It has been my experience, when making the diagnosis of so-called irritable heart, to so frequently find in the social history data which might reasonably have given rise to the symptoms, that in all such cases an exploration of this part of the history is suggested. The above case well illustrates the value of so doing. Such patients are often sent to the heart specialist as probable cases of heart disease.

CASE 4. Boston Dispensary, No. 198947. Nora C., 56 years, single.

Family History. One sister, living and well. Past history negative.

Present Illness. Some gastric distress, chiefly belching of gas, not related to meals. Weakness, especially on exertion. Symptoms have been of gradual onset and are of two to three months' duration. Present weight 114 pounds; was ten pounds more a few months ago.

Physical Examination. Heart: Apex impulse in the fifth space about left midclavicular line. Action regular, rate 120. Systolic murmur at

apex and transmitted to base and axilla. Blood pressure 255/135.

On the second visit to the Heart Clinic, it was noted that the heart rate slowed when the patient was quiet, and accelerated readily on exertion or excitement; the rate ranged from 95 to 136. Patient's eyes filled with tears when questioned as to amount of food taken. Diet: one cup of coffee about 7 A.M.; at 9 A.M., cup of tea and one small piece of toast; at noon, same as at 9 A.M., and occasionally an egg; about 5 P.M., one cup of tea, and another before going to bed. Sometimes takes one slice of toast at 5 P.M.

Social History. Patient and unmarried sister live together. As a result of persistent effort it was learned that they had formerly been comfortably off, financially, but of late their income had become so reduced that it was quite insufficient for their needs. The two sisters had been making great efforts to conceal their plight from the neighbors and their pride caused them to be absolutely unwilling to accept aid from any of the public charities. They lived such a shut-in life that it was difficult for them to get a broader perspective of their situation.

On subsequent visits to the Dispensary, it was noted that the patient was growing progressively weaker, and after learning of the markedly insufficient diet, time was taken to discuss the situation with the patient. It was pointed out that she could hardly expect any gain in strength unless more food was eaten. It was stated that, unfortunately, such a change in income was all too common, but since she could not be held responsible for its decrease, there was no cause for shame. It would be less expensive to the city to assist her now than later, when her condition might have deteriorated to one requiring longer and more costly care. As a result of this and other similar reasoning, the patient is now accepting financial assistance in the purchase of food, and as soon as sufficient strength has been regained will be aided in obtaining suitable employment, so that she may again become self-supporting.

Comment. A case like the above immediately enlists one's sympathy. The patient's personality is such that all in the Dispensary with whom she came in contact are interested in her. While it is not held that an increase in the intake of food will cure the hypertension, it seems certain that lack of nourishment and the associated worry are by all odds the conditions to be attacked first. After this has been done perhaps a better estimate may be made of the hypertension and its treatment.

(My thanks are due to Mrs. Boyers and other members of the Social Service Department for their assistance in collecting these records.)

SUMMARY AND CONCLUSIONS.

Four cases have been cited illustrating the importance of the social history in patients of an out-patient heart clinic.

The social history often discloses why certain patients fail to make an expected improvement.

At times the skillful utilization of such data greatly increases the therapeutic success achieved.

The social history may contain information of value in the diagnosis of that type of patient held to have an "irritable heart."

Attention to the social history opens up a big, broad, humanitarian side of the practice of medicine.

Further justification of emphasis of the social history is found in that it keeps alive the fact that our patients are not mere medical cases, but individuals of flesh and blood.

MODERN ASPECTS OF ACUTE EMPYEMA.

BY WYMAN WHITTEMORE, M.D., F.A.C.S., BOSTON,

Assistant Visiting Surgeon, Massachusetts General Hospital.

In all cases of thoracic surgery there should be a close coöperation between the medical man, the surgeon, the x-ray department, and the laboratory; and this should be the case not only before operation, but also during the convalescence following it.

Many cases of pneumonia have fluid in the pleural cavity at some stage of the disease, and it is of great importance to know whether or not this fluid is sterile. In other words, one must discover whether there is an early empyema present or merely a sterile fluid, for although one may get some suggestion of the correct diagnosis from the history, physical examination and x-ray, yet the only sure proof is examination of the fluid aspirated in the laboratory.

Etiology. Cases may be divided into three groups according to their etiology.

First Group: Those cases that have been preceded by a definite pneumonia. Second Group: Those cases in which although pneumonia may have been present, yet it could not be demonstrated, being hidden by the early and rapid accumulation of fluid in the pleural cavity. Third Group: Those cases which have not been preceded by a pneumonia.

In the first group, that preceded by a definite pneumonia, there are two ways in which the pleural cavity may become infected with a resulting empyema. First, the infecting organisms may work their way through the visceral pleura from the pneumonic area in the lung

and thus infect the pleural cavity. Secondly, the pleural cavity may become infected by the rupture of a small abscess situated in the periphery of the lung. We have recognized this cause of acute empyema for several years, but especially since the use of Dakin's solution became so general in the treatment of these cases, as there is apt to be a pleuro-pulmonary fistula, especially early in the disease, and the use of Dakin's solution immediately causes a severe paroxysm of coughing, the patient complaining of tasting the solution.

The second group, that in which there is doubt as to the empyema being preceded by a pneumonia, is composed of streptococcus hemolyticus cases. In many of these the fluid in the pleural cavity has appeared so early and has increased so rapidly that it has been impossible to demonstrate a pneumonia.

The third group, that in which the empyema has not been preceded by a pneumonia, is a small group. It is made up of two kinds of cases: those empyemas that are secondary to infection outside the lung, as, for example, sub-diaphragmatic abscess, and those following operation in the esophagus. These last are comparatively rare, but the possibility of the occurrence of an empyema following the dilatation of a stricture of the esophagus should be borne in mind. When this occurs, I believe, it is always to be found on the right side.

Diagnosis. The history plays a very important part in making the diagnosis. One should always be suspicious of the pneumonia patient whose temperature comes down to normal and stays there for twenty-four hours and then begins to go up. Many times one is called upon to make a differential diagnosis between an encapsulated empyema that has ruptured into a bronchus and a lung abscess or a bronchiectasis condition. A careful history may show that the patient had pneumonia possibly several months previous to coming to the hospital and this would point more towards an empyema that had been unrecognized than to lung abscess or bronchiectasis. On the other hand, the history may show that the patient had a tonsillectomy a week preceding the infection in his chest, and this would throw considerable evidence towards a lung abscess, as in my series of lung abscess cases, between 65 and 70 per cent. of them are preceded by some operation on the upper respiratory tract. If there was no history of pneumonia or an acute infection of the lung following an operation on the upper respiratory tract, but a gradual incipient onset of cough and increase in sputum, the evidence would point more towards a bronchiectasis.

The final diagnosis depends on the laboratory findings. If the fluid aspirated contains many or few polymuclear leucocytes but no organ-

ism, it is not an empyema (unless one wants to quibble and call it a sterile empyema). On the other hand, if the fluid shows leucocytes plus an organism, it is an empyema, and it does not make any difference whether there are 40 or 90 per cent. polymuclear leucocytes, as it is an empyema in either case. It is important to know what kind of an organism is present, as a streptococcus case should be handled differently from a pneumococcus one. Furthermore, if one is dealing with a staphylococcus aureus case it is well to know it, as it will probably have complications that the ordinary pneumococcus or streptococcus one will not have. I refer to one or more abscesses of the lung, as I have seldom seen a staphylococcus empyema that did not have this complication. The examination of the sputum will sometimes help greatly in making the diagnosis. Recently I have had a case in which the diagnosis lay between an encapsulated empyema and a lung abscess. The sputum showed pus and no organism other than pneumococci, making the diagnosis of encapsulated empyema almost certain, as in lung abscess there are several different kinds of organisms always present.

One may say, what is the use of having an acute empyema x-rayed if aspiration has already been done and the diagnosis proved. Occasionally there is a case of encapsulated empyema that is not suspected from the physical signs, and it is well to know this as it may be that this should be operated on in a different way from a general empyema. The x-ray should always be taken with the patient in the upright position, as this will show a fluid level and help very much in making the diagnosis, whereas if the plate is taken with the patient lying down, there is merely a generally haziness throughout the diseased side of the chest, and the plate is not of very much value unless there is such a large amount of fluid that the heart and great vessels are displaced. Sometimes the x-ray is of great value in clearing up the diagnosis in the cases of small encapsulated empyema that are not found with the aspirating needle. Not infrequently, we see a case which has all the classical signs of an empyema below the angle of the scapula, but we are unable to get anything with the aspirating needle. In these cases the x-ray often shows a small empyema high up at the level of the 4th rib, which is then easily found at operation and the diagnosis of the x-ray proved to be correct.

Although physical examination is of great value, and in many instances throws much light on the case, yet in others it is very disappointing. There is no question but that in some cases it is impossible to be sure whether or not there is fluid present in the pleural cavity. In the wave of influenza bronchopneumonia cases several years ago this was very

noticeable, as in so many of these it was impossible to be sure of the presence or absence of fluid. I believe the most reliable sign of fluid is the absence of tactile fremitus.

Operation: There are two practical surgical techniques for the treatment of acute empyema. The first is the open operation or rib resection. This should be used in the old acute cases in which aspiration shows a thick pus, as in this group we know that the lung is adherent and that an open pneumothorax does no harm. It should be used in the encapsulated empyemas, and in those in which operation has been preceded by several aspirations. If the Carrel-Dakin technique is correctly carried out the convalescence will be much shorter and more satisfactory than that which any other technique can produce. If this technique is to be used it is probably not absolutely necessary to have the most dependant drainage. On the other hand, if the case is in the country, where it is impossible to get Dakin's solution, then the most dependant drainage possible is essential. I believe that in this group of cases irrigation with normal salt solution will hasten the convalescence considerably.

The second practical surgical technique is the closed suction method—that is, draining the pleural cavity without allowing air to enter it. This should be used in the desperately sick, regardless of whether the pus aspirated is thick or thin: this operation being done with the hope of tiding the patient over his critical condition, after which something more radical can be done if necessary. It should be used in the streptococcus cases, and also when one can get a case early, by which I mean when the fluid aspirated is a thin pus containing an organism.

We know that there is every argument against early operation by the open method, as the acute pneumothorax produced causes a high mortality; but there is no argument against this closed suction method in the early cases, as it is merely an aspiration so arranged that it does not have to be repeated and the pleural cavity can be sterilized by means of it. Draining the pleural cavity early, without allowing any air to enter, has many advantages over delayed drainage. In the early stage the lung is not adherent, but merely compressed by the fluid, and if one drains the fluid off without allowing air to enter, the lung will quickly expand; and provided air does not enter the pleural cavity, it will stay expanded. In early drainage such complications as septicaemia, pericarditis and pyaemia are much lessened; also the danger of small pockets becoming walled off from the general cavity is lessened. In fact, I have never had a secondary pocket in any so operated upon. One of the most frequent causes of chronic empyema—too late drainage—is largely done away with.

The closed suction method is so simple and has saved so many lives in the past, and, if used in the correct cases, will continue to save so many in the future, that it seems worth while to describe it again. This method has been much simplified since it was originally used. Some years ago we gave up the electrical suction pump and began using a large 4 oz. glass syringe for suction and irrigations, and this has proved more satisfactory than the pump.

A No. 22 French catheter is put into the pleural cavity, by means of a large trocar, between the 8th and 9th ribs. This is shut off with a hemostat before being put in and kept shut off all the time except when aspiration of the fluid is being done or irrigations are being carried out. The catheter being sewed in tight and fastened also with adhesive plaster, the fluid is gradually removed. In cases in which there is a large amount of fluid we take off about 3 or 4 oz. every twenty minutes until the cavity is dry. At this time we begin irrigations with normal salt solution. These are kept up every two hours or the first twenty-four hours and then irrigations with Dakin's solution are begun. This should be used every two hours, and it is well to do one irrigation with salt solution once each twenty-four hours to prevent the catheter becoming clogged. On the third day following operation, and every day after this, the skin around the catheter should be gone over with iodine for an area of 2 inches. In this way a secondary infection with staphylococci will almost always be avoided. Dakin's solution in itself tends to prevent a secondary infection, but does not always do so, and iodine is a great aid.

The only proof of an empyema being cured is when there are no longer any organisms in the pleural cavity or the sinus. The most reliable test is to take a smear after all irrigations have been stopped for twenty-four hours. When we have three tests taken at forty-eight hour intervals that show no organisms we consider the pleural cavity sterile and remove all drainage apparatus, and to date we have never had a recurrence. One must not be misled by the presence of many leucocytes, as these will always be present. On the other hand, in following the exact Carrel-Dakin technique of taking a smear when no irrigations had been done for only two hours, and considering the pleural cavity sterile when the smear showed not more than one organism to four or five fields, we have been disappointed several times in having a recurrence of the empyema.

Anaesthesia: Local anaesthesia is without question the best anaesthesia to use in all cases of empyema. It can, of course, be used in all adult cases and in practically all children and infants. It is only very rarely that it is necessary to give any infant a general anaesthetic.

It is very simple to introduce a catheter in the closed method under local anaesthesia, and one or more ribs can be resected with ease, either by blocking the intercostal nerves near the site of the operation or by paravertebral anaesthesia. If it is impossible to use a local anaesthetic, and a general one must be used, gas oxygen, given by an expert, is the best; but in the desperately sick, and in those cases in which the empyema has perforated a bronchus, it is a very dangerous procedure. It is dangerous in this latter group of cases as the patient may actually drown in his own pus, and if he does not do this he can easily spread the infection into the other lung.

We no longer turn the patient onto his sound side with the empyema side up, as this may prove dangerous. It is better to operate with the patient sitting up in much the same position that the medical man uses for aspiration or else lying prone on his face with his arms stretched along side his head. This is a most excellent position in which to operate.

In the acute cases that have become healed one often leaves a cavity varying in size, but this cavity is sterile and will give no further trouble, as it gradually disappears by the lung expanding to fill it. This is interesting and important to recognize as it is quite different from what takes place in a chronic case, where the only cure is to obliterate the cavity before allowing it to close. It is a simple matter to sterilize a chronic cavity and get the sinus to heal, but there will always be a recurrence sooner or later as long as there is any cavity in a chronic case.

Dakin's solution, if correctly made and correctly used, will sterilize the pleural cavity more rapidly than any other solution. It is true that an occasional case does brilliantly with normal salt solution irrigations only, but this is rare, and it is interesting to take one that has been on salt solution irrigations for two or three weeks and put it on Dakin's solution, as immediately there are masses of fibrin noticeable which tend to clog the drainage tube. These masses of fibrin are, I believe, particles of the pyogenic membrane which is being broken up and dissolved by the Dakin's solution. In cases in which there is a pleuropulmonary fistula, Dakin's solution will cause severe paroxysms of coughing, and if these are prolonged they may throw the patient into a state of temporary collapse. As it is possible to have a pleural reflex set up by irrigating the pleural cavity with Dakin's solution or any other solution, in these cases, which are extremely rare, it is hardly fair to blame the Dakin's solution for the condition, as it is probable that using water or salt solution would have had the same effect. I have never seen any alarming hemorrhage from the use of Dakin's solution in the pleural cavity.

In all cases there will be a slight bleeding from the healthy granulation tissue being irritated by the solution, which often occurs towards the end of the treatment when the cavity is nearly sterile, but this is of no consequence except as a sign that the pleural cavity is approaching the stage of sterilization.

The after-care should not be confined to the sterilization of the empyema cavity alone, but the general condition of the patient should be built up. Breathing exercises should be begun as soon as the patient's condition will permit. We still believe in and use the old-fashioned blow bottles and can usually begin the use of these in two or three days after operation. The patient should continue to use these, not only until healed, but also for several months afterward. Breathing exercises and setting up exercises should be insisted on when the patient is able to be up and about. These should be faithfully carried out for many months with especial care, not only to get the lung to work fully again, but to prevent any curvature of the spine.

The golden time to cure a case is when it is still acute and not after it has become chronic. The pneumoecococcus cases should be entirely cured—that is sterile and healed—in from four to six weeks; the streptococcus ones generally take about a week or ten days longer, and the staphylococcus ones vary considerably. Some will heal in four to five weeks and others, especially those which are so commonly complicated with multiple small abscess of the lung, will take much longer. For a long time we have not sent any cases out of the hospital until entirely healed. The days in which these cases were operated on and sent out of the hospital with a drainage tube still in, many of them to become chronic cases, are, I hope, gone forever.

ACUTE ETHMOIDITIS WITH ORBITAL ABSCESS. WITH CASE REPORT.*

By HAROLD J. GIBBY, M.D., WORCESTER, MASS.

Assistant Surgeon to the Ear, Nose and Throat Service, Memorial Hospital

"ACUTE empyema of the ethmoid cells alone is, generally speaking, an uncommon affection, at least in our country" (Skillern¹). A case occurring in my practice during the past year presents enough unusual features to be of interest.

Anatomy.—The ethmoid labyrinth embraces all that portion (of the head) lying between the two lateral plates of the orbit. It is composed of two capsules with a partition

*Read before the Staff of the Memorial Hospital, Worcester, Mass.

(perpendicular plate of the ethmoid) between. The capsules have a prolongation at their internal inferior angles which correspond with the middle turbinates . . . the ethmoid occupies approximately one-half the entire space between the floor of the nose and the cribiform plate."²

The literature is rich in descriptive material and case reports of ethmoid and frontal sinus empyema, complicated by orbital phlegmon or orbital abscess, but the case I wish to report has three unusual points of interest, namely: (1) The apparently obscure etiology. (2) The short time elapse. (3) The slight disintegration of bone, in view of the severity of the symptoms.

(1) Empyemas of the ethmoid and frontal sinuses are, as a rule, in the nature of acute exacerbations of chronic inflammatory conditions affecting these labyrinths; the ostiums or outlets become occluded by hyperaemia or hypertrophy of the mucous membrane covering, by polypoid growth, by inspissated pus and mucus, or by an enlarged middle turbinate filling the middle passage of the nose and preventing free discharge of the bacterial products.

A severe coryza superimposed on a chronic inflammatory condition is probably the most common cause of empyema of the ethmoid and frontal sinuses, which in turn forms the focus for the orbital infection. The contents of the orbit are infected either through direct extension of the pus process by necrosis of the orbital plate and actual contact, or by metastasis by way of the ethmoid veins.

The so-called idiopathic cases can usually be traced to preceding systemic diseases, such as measles, scarlet fever, diphtheria, influenza, and many others.

My case gives no history of recent infectious disease or nasal trouble of chronic nature. The adenoids and tonsils were hypertrophied. A mild coryza made its appearance twelve hours before the eye symptoms became pronounced.

(2) Short time elapse. In 1919 Dr. Ira Frank³ reported a case of fulminating ethmoiditis with metastasis occurring five days after the incidence of influenza. After a careful search of the records he believed this to be the shortest time elapse reported up to that date. My case went to bed with a mild coryza, and one nostril occluded, and awoke in the morning with protruding eye, and all the classical symptoms of abscess of the orbit. Skillein⁴ reports a case similar to mine in time but with a well-defined history of previous nasal disease.

(3) Slight disintegration of bone. Probably the time element enters here; not sufficient to have broken down the septa between the cells. No caries of the frontal bone was dem-

onstrated and the mucous membrane lining the frontal sinus was pink and healthy.

Importance of Early Operation.—Blindness, partial or complete, temporary or permanent, is a frequent symptom where there is sufficient cellulitis within the orbit to produce exophthalmos. Skillein says, "the course of the infection is backward, along the course of the optic nerve, and will quickly penetrate the cranium, causing lethal intra-cranial complications."⁵

Prompt measures are, therefore, indicated to evacuate the pus, relieve tension, and remove necrotic bone.

Choice of Operation.—Intranasal operations for the exenteration of the ethmoid and enlarging of the naso-frontal duct are advised by many surgeons. The nostril is usually tightly filled by the swollen turbinate, and there is frequently present a deflection of the nasal septum toward the affected side; indeed, the narrowing caused by this deviation being a factor in the production of the empyema. The hemorrhage is profuse, further obscuring the field of operation. A modified Killian operation, by the external route, presents the certain advantages of speed and a clear view of the parts. It has the disadvantage of scarring, usually aggravated by infection of the wound and consequent delayed healing. The orbital plate must be removed in part, the intra-orbital abscess evacuated, and as this region cannot be seen or palpated through the nose the external operation would seem to be the method of choice in this emergency.

Case History.—R. N., age 12 yrs. Admitted Memorial Hospital, Sept. 13, 1920. C. C. Pain and swelling in left eye. P. H. Measles when an infant; pertussis 4 mo. ago. Habits. Appetite good, sleeps well, has not lost weight. Present Illness. Began 3 days ago with coryza; 2 days ago on waking in morning found that left eye was greatly swollen and protruding. Double vision, lids thick, edematous, and red. Eye painful and with a very painful spot on side of nose above inner canthus. Slight nasal discharge. The eye became more swollen and painful.

Physical Examination.—Well-nourished, well-developed white boy. No infection of ears or throat. Tongue clean. Left eye, marked exophthalmos, the eye protruding forward and outward; lids thickened, red, and closed over eyeball. Nose, middle and inferior, turbinates completely block left nostril; very little thin discharge. Right nostril normal. T. 102.2, P. 90, R. 20. W. B. C. 12,400. Urine normal. Neck, thorax, abdomen, etc., normal.

Notes.—Sept. 14. Case seen in consultation and referred to my service; advised immediate exenteration of ethmoids; permission for operation not obtained until following day.

Operation.—Sept. 15. A curved incision through eyebrow, continuing down nose, internal to lachrymal sac. Periosteum elevated without disturbing pulley of trochlear muscle or tear sac. Anterior ethmoid entered with gouge; thick, light yellow pus encountered under slight pressure. Rongeur used to enlarge bone wound. Frontal sinus filled with pus, mucous membrane normal and not removed. Anterior ethmoid cells filled with pus but not necrotic. All septa and cell walls in ant. ethmoid region removed and a large, smooth passage everted through bulla region, giving free drainage. Part of orbital plate removed but no abscess located within orbit. It was not necessary to clean out the posterior ethmoid or sphenoid cells.

Plain gauze drain passed through this artificial opening, the proximal end lying in the ethmoid-frontal region, the distal protruding from the nostril. Wound closed with horsehair sutures. Culture of pus from cavity showed Staph. Aureus. Temperature did not rise above 99 following the operation. Drain removed on the second day. Exophthalmos disappeared by fifth day. Wound opened sixth day; profuse discharge of pus from wound and into naso-pharynx.

October 2.—Discharged from hospital, wound still discharging; sight in both eyes normal.

Subsequent History.—All nasal pus ceased in two weeks. Two small sequestra removed about one month after operation. Wound healed in six weeks.

February, 1922, a year and three months following the operation: tonsils and adenoids have been removed by myself. Still has occasional mild coryza, no return of ethmoid symptoms. Circular depressed scar, about 2 cm. in diameter, not very noticeable.

HEART DISEASE IN INDUSTRY.

By W. IRVING CLARK, JR., M.D., WORCESTER, MASS.

THE majority of males in the Eastern States are connected directly or indirectly with some form of industry. Most of those connected with industry are doing more or less laborious work and depend upon this for their livelihood. Tuberculosis has for years past been recognized as one of the prevalent diseases among industrial workers. It is only recently that the attention of the public has been called to the prevalence of cardiac disease. While cardiac disease does not produce the early mortality of tuberculosis, for the past three years

organic heart disease has caused more deaths than tuberculosis. Dublin,¹ in a résumé of the importance of organic heart disease to the community, gives the following statistics:

Prevalence.—Two per cent. of the persons examined by insurance companies are rejected because of serious heart defects.

Two per cent. of industrial workers are found on careful examination to be subjects of serious heart defects.

Two per cent. of those examined in the draft and camp examinations by army medical examiners were rejected on account of serious heart defects.

One and one-half to two per cent. of the children examined in the schools show serious heart defects.

Effect on Longevity.—It has been found that heart disease has a serious effect on longevity, reducing the span of life by practically one-half.

Mortality.—The death rate from organic heart disease for a series of recent years has been fairly stationary, its rise to first place being accomplished by the fall of tuberculosis.

Under 25 years of age organic heart disease causes as many deaths as typhoid fever.

Between 25 and 34 years organic heart disease causes as many deaths as lobar pneumonia.

Between 35 and 44 years organic heart disease causes more deaths than Bright's disease.

After 45 years organic heart disease shows a higher death rate than any other cause.

With these figures in mind it is evident that approximately two per cent. of all workers are liable to the interruptions of steady work and other disabilities to which patients with organic heart disease are subject.

White,² in an admirable paper recently published, says: "There is not, as far as I know, any industrial heart disease." The majority of industrial physicians will agree with this statement, which means that the heart disease found in industry is, in the majority of cases, directly traceable to some condition not connected with industry, and that thus far, although there are substances which cause D. A. H. and cardiac syncope, no industrial poison known has a specific effect on the heart resulting in disease. Arteriosclerosis, as he points out, is a very important cause of heart disease, but whether arteriosclerosis can be attributed solely to work in industry is questionable. That it may be due to lead poisoning is recognized.

In 1914, Cabot, following an analysis of 600 hospital cases of "failing heart," found that 93 per cent. fell into one of the four following classes: (1) Rheumatic, (2) nephritic, (3) arteriosclerotic, (4) syphilitic. This is probably as satisfactory an etiological classification as can be found to use in industry.

The prevalence of tonsillitis in industry is recognized. At Norton Company, in 1919-1920, this disease stood fifth on the list of diseases causing lost time, rheumatism standing sixth. The latter term, however, grouped both acute and chronic rheumatism and is therefore of little value. A large factory employing over 10,000 workers in the Middle West shows tonsillitis to be the second most prevalent disease and rheumatism the third.

The amount of nephritis in industry is more or less an unknown question. While in certain industrial medical departments some statistics are available, not enough thorough work has been done to make these of much value.

Syphilis, while it is recognized frequently in its active stage, is seldom diagnosed in industry after the secondary stage. Occasionally the condition of the heart or some other organ suggests the advisability of a Wassermann, but no routine laboratory work is possible in the majority of industrial clinics.

The amount of arteriosclerosis is likewise largely conjectural. It will be seen from this that the attention of industrial physicians has been called definitely to the prevalence of tonsillitis and rheumatism in industry, but that the other etiological facts have not as yet been of sufficient importance, because of their symptoms and resulting disability, to make any reliable statistics available.

Judging from Norton Company experience and records, I feel that the majority of cases of heart disease are secondary to germ infection; that in most of these cases the germ was that harbored in the tonsils or causing rheumatic fever; that of the remainder, most were secondary to influenza and were probably of streptococcal origin, while very few in any way can be linked with syphilis.

In industrial work, as in cardiac clinics, the most frequent heart lesion encountered is chronic mitral disease showing insufficiency of the valve without stenosis. At Norton Company we have been very careful not to include in our statistics any case in which the murmur was not transmitted to the axilla or back, but even after a rather rigid investigation, 63 of our 76 recorded heart cases appear to be true cases of mitral insufficiency. Next in frequency in our experience is aortic insufficiency with mitral incompetence. Other cardiac conditions are rare. The average age of our patients was 37 years, showing that heart disease as it exists in this particular factory allows work over a long period of time. This is further emphasized by the fact that only 11 of the 76 had any symptoms from their hearts while working, and in only three cases was it necessary for the worker to lose more than a very few days because of decompensation. Placed in tabular form, our statistics are as follows:

Business; Manufacture of abrasives, grinding wheels and grinding wheel machinery. Average number of employees, 3200; number of records reviewed, 8100; number of cases of heart disease, 76; per cent. of employees having heart disease, .95 per cent; number of cases of heart disease applying for work but rejected because of condition in 1920, 4.

One of the cardiac classifications adopted by the Association of Cardiac Clinics in New York and quoted by White is as follows: (1) Those able to carry on their habitual activities (without symptoms of distress); (2) those able to carry on slightly curtailed activities; (3) those able to carry on moderately decreased activities; (4) those able to carry on only greatly diminished activity; (5) those unable to carry on any of their habitual activities.

Classifying Norton Company cases along these lines we find: Class 1, 52 cases; Class 2, 13 cases; Class 3, 8 cases; Class 4, 3 cases; total, 76 cases.

In further tabulating we have decided to record the following: (1) Evidence of disease; (2) age of patient; (3) response to exercise and work; (4) history or physical findings suggesting previous tonsillitis or rheumatic fever; (5) history or evidence of previous venereal disease; (6) condition of teeth; (7) symptoms suggesting cardiac decompensation while at work.

Placed in tabular form, the statistics are as follows:

Mitral Systolic Murmur (organic).....	60
Mitral Systolic Murmur with marked irregularity	3
Aortic Diastolic and Mitral Systolic Murmur ..	9
Presystolic Murmur at Apex (not Flint)....	1
Hypertrophy and dilation with marked irregularity	1
Aortic Diastolic Murmur.....	1
Age (average)	37 yrs.
Response to Exercise and Work:	
Good	53
Fair	18
Poor	2
?	3
Rheumatism or Tonsillitis, history or symptoms	21
Venereal Disease:	
Gonorrhea	2
Syphilis	0
Poor Teeth	40
Heart Symptoms while at Work.....	11

It is interesting to note that the number of workers with heart disease at Norton Company is one-half the number usual in industry as a whole. It cannot be said that this is due to the physical examination before work as only four cardias were rejected in one year. The probable explanation is that the worker usually finds his own physical level. The cardiac quickly realizes that there are certain kinds of work he is unable to do and adjusts his life

accordingly. The result is that only those are found in unskilled and semi-skilled work who are physically able to do the work. Arguing from this, one would expect to find a correspondingly high percentage of cardiac cases in the more sedentary occupations. I have been unable as yet to find out whether this is a fact.

In considering work as an etiological factor in cardiac disease, though this may have played an important part in the past and possibly does today in certain industries which require heavy work for long hours, the tendency throughout the country is to reduce the work schedule to 48 or 50 hours a week. This, with the elimination of alcohol, may have an interesting effect on the hearts of the present rising generation. However, after considering the matter in as unprejudiced way as possible, one cannot help feeling that if pathogenic bacteria were eliminated the heart could stand any reasonable amount of work without resulting disease. What can be done for the individual cardiac in industry? If the hypothesis that cardiacs in industry find their own level is correct, the problem for the industrial physician is to prevent strain. This requires (1) A careful primary examination and record; (2) an adjustment of work when this appears advisable; (3) reexaminations at stated intervals; (4) careful instruction as to proper living outside of factory work.

By following such an outline organic heart disease may carry on in industry with minimum risk and maximum value to the diseased individual and the community.

THE INFANTILE HEART IN ADULT LIFE.

BY LOUIS FAUGERES BISHOP, A.M., M.D., Sc.D.,
F.A.C.P., NEW YORK.

*Consultant in Heart and Blood Vessel Diseases,
Lincoln Hospital, New York City, New York.*

ONE of the hardest things to realize during the transition from a practice of medicine founded upon pathologic anatomy, to a practice of medicine founded upon pathologic physiology, has been that important conditions, even of a physical nature, can exist during life and yet be overlooked at post-mortem examination.

Vaquez¹ and others have come to our rescue in their observations in this one particular, namely, that a very distinct dilatation in the

region of the conus, meaning an enlargement of the pulmonary artery, showed no corresponding post-mortem condition by the methods employed in such work up to the present time. In fact, the examination of the right side of the heart and pulmonary circulation is, as a rule, carelessly carried out.

The electrocardiogram, through the revelation of right-sided predominance, has brought the pulmonary circulation into greater prominence. As a result, many careful observers have reached the conclusion that embarrassment of the right side of the heart, due to disease or congenital defect dated from early life, is not nearly so rare as was formerly supposed.

No matter how many hearts we examine we do not find any two hearts alike, any more than we find no two faces exactly alike, no matter how large the group. However, just as people resemble each other, and can be grouped into many categories, so hearts can be grouped. From time to time, people have called attention to particular types, and the value of this grouping has been in the relationship of the groups to health and disease conditions studied. A group which has presented itself to me more and more, as I have studied it, I have ventured to give the name of the "Infantile Heart," just as Balfour² named the Senile Heart.

The infantile heart is met with as a recognizable condition from the tenth year of life onward. I have thought that I could identify it even in the fifties and sixties. These people have a heart characterized by a relative right predominance (Figure 1), by the persistence of sinus arrhythmia at all ages, by a limitation of cardiac response, by a tendency to attacks of palpitation, and also by a consciousness of the heart that average people do not have. They often show a blowing murmur in the pulmonary region.

The pathologic anatomy I have not yet had an opportunity to work out, and must present this as a clinical group.

The man with an infantile heart can go as far as he will, without injury to the heart, because his wind gives out and he must stop. The left side of the heart is not overdeveloped because the pulmonary circulation, failing first, the left ventricle never has had any opportunity to be increased in size, such as comes to those who indulge unduly in athletic contests.

A very promising football player recently came under observation because a peculiarity was detected in his heart and the conclusion was reached that it might prove dangerous for him to indulge in the game. He was a man of tremendous build, capable of great effort for a short time. He showed some distress on breathing. An examination showed the syndrome of an infantile heart, namely, a right predominance, sinus arrhythmia, a his-

FIGURE 1.—An electrocardiogram showing a relative right ventricular preponderance. There is one ventricular extrasystole in the third lead.

tory of palpitation, and a soft blowing murmur above and to the left of the middle of the sternum.

On the ground that he probably would not hurt himself, since he would have to stop before any damage was done, he was allowed to continue to play football.

Indeed, this has been the policy in athletics with regard to boys suffering with this syndrome. They are allowed to go as far as they are able without distress. Distress comes earlier in these cases than in a compensated mitral condition or in an aortic regurgitation.

This group has proved to be a useful one as the repository for some conditions that are not definite enough to be labeled congenital heart disease, and which do not present the findings, symptoms or history of acquired cardiac defect.

All symptoms comprised in the syndrome must be present, and can usually be brought out by careful questioning. Of course, the predominance and the sinus arrhythmia must be determined by the examination with instruments of precision. The fluoroscope usually shows besides a centrally located heart shadow (Figure 2), a fairly definite predominance in the region of the conus. The palpitation may not be recognized by the person, because he does not know that other people can do things without inducing a rapid heart, which he cannot.

It is purely physiologic for a child to have a rapid heart after violent exertion, so this is a quantitative symptom. The same is true of

FIGURE 2.—Roentgen ray photograph taken at a distance of six feet to show centrally located heart typical of these patients.

precordial distress. It is often better obtained by observing the person under exercise than by depending on the statement of the person under examination.

An interesting problem has been the recog-

mission of this condition in later life. It has seemed that, on several occasions, I could surmise that this condition had existed in the early life of people who later developed extremely high blood pressures (I mean, 230 and 240, and the like), which could not be accounted for in any way, and which were carried with an unusual degree of tolerance. In one instance, the son of such a man showed definite evidence of having an infantile heart.

No one who has studied high blood pressure for a long time doubts the existence of these strange examples of high blood pressure in people without any discoverable disease and showing very few symptoms. They present anomalous circulatory relationships, and, as stated above, may be accounted for as the advanced development of infantile heart. They differ from the ordinary high blood pressure cases in that their hearts are not markedly the subject of a left predominance. There may even be a right predominance at an advanced age.

A certain number of infantile hearts seem later to conform to the normal type. In other words, in popular language, the condition is outgrown.

The illustration is a typical example of an infantile heart in an adult.

THE TREATMENT OF INSOMNIA.

RYDOLF (*Brit. Med. Jour.*, March 11, 1922) divides insomnia into nine classes as follows:

1. Dolorous.
2. Digestive.
3. Cardiac and dyspnoeal.
4. Cerebrospinal and neurotic.
5. Psychic.
6. Insomnia due to physical fatigue.
7. Genito-urinary.
8. Febrile and auto-toxic.
9. Toxic.

He summarizes his remarks in regard to this subject thus:

1. All cases of insomnia may be classified as being produced either by an increase in the excitability of the nerve centres, or from an increase in the afferent stimuli reaching those centres, or by both.

2. In every case the afferent stimuli should be reduced as much as possible, and to this end, after the environment has been made as appropriate as practicable, physical therapy, especially hydrotherapy, should be employed.

3. If the excitement of the cerebral centres remains too great, then this may have to be reduced by the employment of hypnotics, and here the mildest should first be used.

4. Opium and its derivatives should never be employed in the treatment of chronic insomnia, or in that dependent upon abnormal mental states.

[J. B. H.]

AORTIC REGURGITATION.

RUSSELL-WELLS (*The Practitioner*, Feb., 1922) sums up his opinion on aortic regurgitation and its treatment in the following paragraph:

"To sum up, digitalis should only be given, if at all, with the greatest caution in cases of pure aortic regurgitation. It may be given with perfect safety when there is some lesion of the mitral valve which insures permanent mitral regurgitation as well as the aortic incompetence. It may be given with much benefit when there is secondary mitral regurgitation, but as soon as the mitral valve shows signs of becoming competent, it should be stopped before absolute competence is reached. Strophantus is thought to be safer than digitalis because it is considered to affect the peripheral vessels less, but the same principles apply."

[J. B. H.]

TUBERCULOUS ABSCESSSES OF THE CHEST WALL.

ATCHINCLOSS (*Ann. of Surg.*, April, 1922) writes as follows:

Tuberculous abscesses of the chest wall are frequent enough to be of importance to the general surgeon, yet rare enough for many surgeons not to have had enough cases for study as to their pathogenesis and treatment.

There is a widespread opinion that such cases are, in the majority of instances, due to a "tuberculous rib" as the distributing or "primary" focus. The cases studied would indicate this not to be the case. The ribs did not show tuberculosis except after pieces of them had been removed and continuation of the tuberculous infection had occurred with secondary infection.

The distributing factor for the abscess seems to be from those structures immediately beneath the bony, cartilaginous or muscular chest wall. The lungs, the pleura and the mediastinal lymphatics seem pre-eminently responsible. The abscess is frequently deep as well as superficial to the chest wall; e.g., the "collar-button" or "dumb-bell" abscess.

The abscesses occur chiefly on the antero-lateral aspects of the chest wall rather than posteriorly.

The associated tuberculous lesions are varied in number and importance. They may or may not be more important than the abscess.

An extraordinarily large amount of calcium deposit may be present. The x-ray plates showing calcium are rather characteristic.

The story of influenza or an acute pulmonary condition may determine the onset of the abscess formation.

As complete excision of the tuberculous focus, leaving vascular, well-nourished walls to come together, with filling in dead spaces by muscle and pressure bandage and primary closure of wound, is the treatment, though this may have to be modified by an associated lesion.

[E. H. R.]

The Massachusetts Medical Society.

PROCEEDINGS OF THE COUNCIL.

ANNUAL MEETING, JUNE 13, 1922.

THE annual meeting of the Council was held in the amphitheater of Building A at the Harvard Medical School, Boston, at 12 o'clock noon, June 13, 1922. The President, Dr. John W. Bartol, was in the chair and the following 115 Councilors present:

BARNSTABLE.

W. D. Kinney, Osterville, M.N.C.

BERKSHIRE.

A. P. Merrill, Pittsfield.
B. W. Paddock, Pittsfield.
P. J. Sullivan, Dalton, M.N.C.

BRISTOL NORTH.

Sumner Coolidge, Middleborough, V.P.
W. H. Allen, Mansfield.
F. A. Hubbard, Taunton, M.N.C.

BRISTOL SOUTH.

E. F. Cody, New Bedford.
W. A. Delan, Fall River.
R. W. Jackson, Fall River, M.N.C.

ESSEX NORTH.

R. V. Baketel, Methuen.
T. R. Healy, Newburyport, M.N.C.
G. E. Karth, Lawrence.

ESSEX SOUTH.

P. W. Baldwin, Danvers, V.P.
Loring Grimes, Swampscott.
W. T. Hopkins, Lynn.
J. F. Jordan, Peabody.
W. G. Phippen, Salem.
J. W. Trask, Lynn.

FRANKLIN.

B. P. Croft, Greenfield.
G. P. Twitchell, Greenfield, M.N.C.

HAMPDEN.

M. B. Hodskins, Palmer, V.P.
A. C. Eastman, Springfield.
J. P. Schneider, Palmer.

HAMPSHIRE.

A. J. Bonneville, Hatfield.

MIDDLESEX EAST.

L. M. Crosby, Wakefield.
W. H. Keleher, Woburn.
Ralph Putnam, Winchester.

MIDDLESEX NORTH.

W. E. Jackson, Lowell.
J. H. Lambert, Lowell.

MIDDLESEX SOUTH.

E. H. Bigelow, Framingham, M.N.C. and C.
E. W. Barron, Malden.
F. G. Curtis, Chestnut Hill.
John Puff, Charlestown.
W. E. Fernald, Waverley.
C. B. Fuller, Waltham.
C. E. Hills, Natick.
F. R. Jonett, Cambridge.
H. J. Kenney, Everett.
S. F. McKeen, Allston.
C. E. Mongan, Somerville.
C. E. Painter, Newton, C.
W. D. Ruston, Somerville.

J. W. Sever, Cambridge.
C. H. Staples, Malden.
E. H. Stevens, Cambridge, M.N.C.
A. K. Stone, Framingham Center, Treasurer.
Fresenius Van Nijls, Weston.
H. R. Webb, Arlington.
W. S. Whittemore, Cambridge.
Alfred Worcester, Waltham, Ex-P.

NORFOLK.

W. J. Walton, Dorchester, V.P.
W. B. Batchelder, Dorchester.
E. H. Baxter, Hyde Park.
W. L. Burrage, Jamaica Plain, Secretary.
J. A. Cecchi, Dorchester.
D. G. Eldridge, Dorchester.
T. P. Greene, Roxbury.
F. C. Jillson, Jamaica Plain.
G. W. Kaan, Brookline.
Bradford Kent, Dorchester.
H. H. Powers, Brookline.
Victor Safford, Jamaica Plain.
Augusta Williams, Brookline.

NORFOLK SOUTH.

C. S. Adams, Wollaston.
G. M. Sheahan, Quincy.

PLYMOUTH.

A. L. Beals, Brockton, V.P.
W. C. Keith, Brockton.
Gilman Osgood, Rockland.

SUFFOLK.

J. S. Stone, Boston, V.P.
J. L. Ames, Boston.
S. H. Ayer, Boston.
J. W. Bartol, Boston, President.
V. Y. Bowditch, Boston.
J. T. Bottomley, Boston.
J. E. Briggs, Boston.
M. E. Champion, Boston.
L. J. Cummins, Boston.
Lincoln Davis, Boston.
W. H. Devine, South Boston.
Channing Frothingham, Jr., Boston.
J. E. Goldthwait, Boston.
W. C. Howe, Boston, M.N.C.
J. C. Hubbard, Boston.
H. T. Hutchins, Boston.
E. A. Locke, Boston.
F. T. Lord, Boston.
F. B. Lund, Boston.
G. B. Magrath, Boston.
E. H. Place, Boston.
Edward Reynolds, Boston.
Stephen Rushmore, Boston.
D. D. Scannell, Boston.
C. M. Smith, Boston.
E. W. Taylor, Boston, C.
L. P. Tingley, Boston.

WORCESTER.

G. E. Emery, Worcester, V.P.
F. H. Baker, Worcester.
W. P. Bowers, Clinton, Ex-P.
L. R. Bragg, Webster.
W. J. Delahanty, Worcester.
G. A. Dix, Worcester.
M. F. Fallon, Worcester.
Homer Gage, Worcester.
David Harrower, Worcester, M.N.C.
E. L. Hunt, Worcester.
A. W. Marsh, Worcester.
L. C. Miller, Worcester.
C. B. Stevens, Worcester.
G. O. Ward, Worcester.
F. H. Washburn, Holden.
S. B. Woodward, Worcester, Ex-P.

WORCESTER NORTH.

J. G. Henry, Winchendon.
H. R. Nye, Leominster, M.N.C.
A. H. Quessy, Fitchburg.

The Secretary read the minutes of the last meeting and they were approved.

The Secretary read the names of the Nominating Committee by districts, the following answering to their names:

BARNSTABLE,	MIDDLESEX SOUTH,
W. D. Kinney,	E. H. Stevens,
BERKSHIRE,	NORFOLK,
P. J. Sullivan,	D. G. Eldridge,
BRISTOL NORTH,	NORFOLK SOUTH,
F. A. Hubbard,	G. M. Sheahan,
BRISTOL SOUTH,	PLYMOUTH,
R. W. Jackson,	W. C. Keith,
ESSEX NORTH,	SUFFOLK,
T. R. Healy,	W. C. Howe,
ESSEX SOUTH,	WORCESTER,
W. T. Hopkins,	David Hartower,
FRANKLIN,	WORCESTER NORTH,
G. P. Twitchell,	H. R. Nye,
MIDDLESEX EAST,	
Ralph Putnam,	

The Nominating Committee retired.

The President made the following remarks:

The end of our year has been marked with sadness. On April 15 died Edward John Brearton of Dorchester, a member of the Council, in the full possession of his faculties, at the age of 44. He was educated in the public schools of Boston, graduated from Tufts College Medical School, was a member of the A. E. F., returned with the commission of captain, and resumed his practice in Dorchester. A quiet, unpretentious local practitioner, he has been sorely missed in the locality in which he practised.

Yesterday morning died another Councilor, Edward Hall Nichols of Boston. He was born in 1864 in Reading. Always taking a prominent place in the life where he was situated, a prominent part in college activities from first to last, assuming always a position of leadership, able, fearless, impetuous, farnk to a fault, the affection for him in the minds of all of us here is too ripe for me to speak without emotion at our sudden loss.

The year just ended has been a successful year in many ways for the Society. We have passed the 4,000 mark in membership. The duties of the President have been happy duties, especially the ones which brought him in contact with the outlying districts, where he feels that a great deal of helpful work is being done for the welfare of the Society at large; and he comes back from his brief pilgrimages to these districts with a conviction that the tendency of the Society is to become a little bit top-heavy in its membership, that we don't do enough here to bring the whole Society together, with

Suffolk District at 800—we will say—and with the two Middlesex Districts and Norfolk together surpassing that number, it makes an unfortunate concentration in the eastern border of the State. It makes the feeling a definite one in the smaller districts, where they perhaps have 40 members or less, as in Barnstable—it makes them feel a little bit remote in distance and in the matter of contact; and the President feels very much that the future of the Society hangs a great deal on the success of amalgamating all the interests and of creating some diversion. Dr. Alfred Worcester has already made a most valuable effort in that direction in the formation of group meetings. Those meetings should continue. They have gone well in the districts, and the districts are unanimous in wishing them to continue. Your President feels that it is highly desirable that similar meetings shall be held; but further efforts should be made to bring in the real interest that exists, but which feels, I am confident, a little bit aloof.

The committees appointed by the Council to consider the petitions of W. H. Blanchard and T. J. Brennan for restoration to the privileges of fellowship were read and were acted on favorably, it being voted that each be restored under the usual conditions. Committees were appointed to consider eight similar petitions for restoration, as follows:

For A. A. Pastene: W. H. Robey, Jr., G. S. Derby, W. T. S. Thorndike.
For W. A. Millet: J. B. Thomas, B. W. Paddock, C. T. Leslie.
For J. Z. Naurison: A. C. Eastman, M. B. Hods-kins, P. Kilroy.
For J. T. Buckley: R. W. Greene, W. F. French, R. J. Ward.
For W. H. Gallagher: H. T. Hutchins, C. Frothingham, L. Davis.
For H. A. Field: D. G. Eldridge, W. C. Kite, W. A. Lane.
For S. K. Pachanian: J. H. Lambert, C. S. Baker, N. Pulsifer.
For F. R. Tower: G. S. Hill, W. C. Howe, S. Rasmore.

Dr. S. B. Woodward presented the accompanying report of the Committee on Membership and Finance, as to Membership. It was accepted and its recommendations adopted:

REPORT OF THE COMMITTEE ON MEMBERSHIP AND FINANCE, AS TO MEMBERSHIP.

The Committee on Membership and Finance make the following recommendations as to membership:

1. That the following three Fellows be allowed to retire under the provisions of Chapter I, Section 5, of the By-Laws:

Hall, William Dudley, 416 Marlborough Street, Boston.
Hubbard, Elbery Cole, 122 Huntington Avenue, Boston.
Jenkins, Charles Edwin, 10 Prosser Street, Lynn.

2. That the following eleven Fellows be allowed to resign, under the provisions of Chapter I, Section 7, of the By-Laws:

Armstrong, Donald Budd, 570 Seventh Avenue, New York.
Barach, Alvan Leroy, 33 East 6th Street, New York.
Bell, James Francis, Jr., 903 Journal Building, Portland, Oregon.
Butler, David Mathew, 12 Cottage Street, Brooklyn, Mass.
Dearborn, George Van Ness, U. S. P. H. S. No. 42, Perryville, Md.
Eaton, Henry Douglas, Los Angeles, California, with remission of dues for 1921-1922.
Hodgdon, Frank Wellington, Jr., Pasadena, California, with remission of dues for 1920-1921.
Jaujigian, Robert Rupen, Wilkesbarre City Hospital, Wilkesbarre, Pa.
Jedalian, Haimarab S., Fresno, California.
Keown, James Archibald, 42 High Street, Lynn.
Kinne, George Lyman, 265 Maple Street, Holyoke.

3. That the dues for 1921, of Withington, Alfreda Bosworth, now of 23 Rue de la Paix, Paris, France, be remitted, she having been engaged on reconstruction work until August of this year.

4. That the following nine Fellows be allowed to change their district membership, without change of legal residence, under the provisions of Chapter III, Section 3, of the By-Laws:

Allen, Arthur Wilburn, from Norfolk to Suffolk.
Crawford, Francis Xavier, from Middlesex South to Suffolk.
Handy, Harry Tucker, from Plymouth to Norfolk South.
Jones, Chester Morse, from Middlesex South to Suffolk.
Meaker, Samuel Raynor, from Norfolk to Suffolk.
Moir, Marguerite Winifred, from Norfolk to Suffolk.
Parris, Roland Oliver, from Middlesex South to Suffolk.
Sirazusa, James Joseph, from Norfolk to Suffolk.
Wood, Nelson Merwin, from Norfolk to Suffolk.

Respectfully submitted, for the Committee on Membership and Finance,

SAMUEL B. WOODWARD, *Chairman*.

Dr. Woodward prefaced his report with a personal statement on relinquishing the office of chairman, concerning his services to the Society since the year 1888 in the offices of delegate, vice-president, membership in the standing committees on scientific papers, ethics and discipline, state and national legislation, membership and finance, and as president for three years; he regretted that pressure of other work prevented him from further service; he cherished an abiding interest in the Society, and would continue to be a Councilor by virtue of being an ex-president, under the terms of the By-Laws. He read the following report of the Committee on Membership and Finance, as to Finance:

REPORT OF THE COMMITTEE ON MEMBERSHIP AND FINANCE, AS TO FINANCE.

On February 14, 1922, the Council *Voted*, That a motion of Dr. E. H. Bigelow, Chairman of the Committee on Public Health, be referred to the Commit-

tee on Membership and Finance for consideration, this Committee to report back to the Council at this time.

Dr. Bigelow's motion, as transmitted to the Committee on Membership and Finance by the Secretary, read as follows: "Moved, that the Council authorize the expenditure of a sum of money, not to exceed twenty-five hundred dollars (\$2500), for the investigation of health problems in relation to the care of the sick in rural communities in Massachusetts, to see if conditions can be improved; such money to be expended by the Committee on Public Health, should investigation by said Committee demonstrate the need of such work by the Massachusetts Medical Society; all expenditure for this work to be subject to the approval of the President of the Society and the Chairman of the Committee on Membership and Finance."

The vote of the Council was: "That the entire matter be referred to the Committee on Membership and Finance for a report at the next meeting of the Council, with the understanding that the Committee on Public Health will present to said Committee on Membership and Finance, at an early date, a definite, detailed plan for the expenditure of the appropriation asked for."

At a meeting of the Committee on Membership and Finance, held on June 8th, the following vote of the Committee on Public Health was presented to them: "164 Longwood Ave. Public Health Committee, M. M. S., etc., June 6th, 1922. *Voted*, That this Committee ask for \$2500 to finance a field agent to study conditions in rural communities looking toward the development of laboratories and hospital facilities for the mutual benefit of the physicians and the citizens.

(Signed) ANNIE LEE HAMILTON,
Secretary of Committee on Public Health."

This vote of the Committee on Public Health was thoroughly discussed, and the chairman was directed to report to the Council that the Committee on Membership and Finance feel that a properly made survey on these lines might be of value and might at least settle the question whether any action by the Society, or of the community was necessary to remedy conditions now existing; that the Committee believe there may be important work to be done in this direction and that the treasury of the Society is in such condition that the appropriation asked for, namely \$2500, might be made, but failing to find in the only communication received from the Committee on Public Health such a definite, detailed plan as seems called for by the vote of the Council, the Committee on Membership and Finance must report to the Council that from any information as yet furnished them, they do not feel authorized to recommend the expenditure of money.

Respectfully submitted for the Committee on Membership and Finance,

SAMUEL B. WOODWARD, *Chairman*.

Dr. E. H. Bigelow, chairman of the Standing Committee on Public Health, called attention to the fact that his committee had made a report in the official organ of the Society in the issue of May 11, 1922, stating in that report that the Committee could not give a detailed financial estimate of what the proposed work in rural communities called for, according to the vote of the Council last February; he apologized to the Chairman of the Committee on Membership and Finance for not calling his

attention to the report; the committee proposed to put a hard working field agent through the state to survey the field and report. He then read his report for the Committee on Public Health for the past year. (See Appendix No. 1.) Dr. W. A. Dolan moved, and it was seconded, that the report of the Committee on Membership and Finance, as to Finance, be accepted and its recommendations adopted. Dr. Bigelow offered an amendment to the effect that the report be accepted without adopting its recommendations. Seconded. The amendment, being put to a vote, was lost. The Chair explained that the way was open for a reference of the matter back to the Committee on Membership and Finance for a further report by that Committee to the Council. Dr. Bigelow moved to amend Dr. Dolan's motion by adding the words "that \$2,500 be granted to the Committee on Public Health to finance a field agent to study health problems in rural communities." The Chair ruled that such a motion to amend was out of order because it constituted an extraordinary appropriation, which, under the By-Laws, must be referred, before action, to the Standing Committee on Membership and Finance. Dr. Dolan's motion was then put to a vote and passed. Subsequently the report of the Committee on Public Health was accepted by vote.

Dr. C. F. Painter, Chairman of the Standing Committee on Medical Education and Medical Diplomas, read the report of his Committee and also the report of the Delegate, a member of his Committee, to the Conference on Medical Education at Chicago in March, 1922. (See Appendix No. 2.) The President stated that he himself had had a most successful trip to Chicago as a delegate to the Conference on Medical Legislation; he would not report at length because of the lack of time; he favored sending two delegates each year to keep in touch with what was going on in the country at large. The reports were accepted by vote. Dr. Painter presented a revised list of medical colleges, diplomas from which are accepted by the censors from candidates for fellowship, in accordance with the vote of the Council, February 1, 1922. He said that two additions had been made to the previous list and all the medical schools and colleges of the United States and Canada that are approved had been arranged alphabetically instead of by states, as in the past. *Voted*, That the revised list of medical colleges be adopted. The list as printed is a part of this record. Dr. J. S. Stone, Secretary of the Standing Committee on State and National Legislation, read the report of that Committee for the past year and it was accepted. (See Appendix No. 3.) In accordance with the recommendation of this Committee, Dr. S. B. Woodward, who first called the

attention of the Council to the limited amount of income the Society might hold, under the terms of Article X of the Digest, at the meeting of the Council, February 2, 1921, introduced the following motion:

Moved, That the Society be requested to appoint at the Annual Meeting a committee who shall petition the next General Court to enact an amendment of Chapter 15, Section 9, of the Statutes of 1781, so that said statute shall conform to the provisions of Chapter 180, Section 9, of the General Laws of Massachusetts, 1921, relating to charitable corporations, as regards the amount of real and personal property the Society may hold; the intention of this motion being that the proposed amendment shall be submitted for approval to the Council at its October meeting.

The motion, having been seconded, was put to a vote and passed unanimously.

Dr. Homer Gage, Chairman of the Committee of Nine, having charge of the BOSTON MEDICAL AND SURGICAL JOURNAL, reported that the JOURNAL was in a satisfactory condition; he paid tribute to the unselfish labors of the managing editor, Dr. W. P. Bowers, and predicted that before long the JOURNAL could be furnished to the Society for a decreased cost. He presented a financial statement by a certified public accountant of the finances of the JOURNAL from April 1, 1921, to December 31, 1921. (See Appendix No. 4.)

Dr. Walter P. Bowers, who was received with applause, read the report of the Committee on Maternal and Infant Welfare (See Appendix No. 5) which was accepted and its recommendations adopted.

Dr. Edward Reynolds presented the report of the Committee on Cancer (See Appendix No. 6) and it was accepted with the understanding that in future Dr. R. B. Greenough would be Chairman of this Committee.

The Secretary read the following nomination and it was automatically referred to the Committee on Membership and Finance under the provisions of Chapter 1, Section 4 of the By-Laws:

Waltham, May 18, 1922.

To the Council of the Massachusetts Medical Society:

Dear Sirs: Under the provisions of Section 4, Chapter 1, of the By-Laws, we hereby nominate General Leonard Wood, Governor-General of the Philippine Islands, as an honorary member of the Massachusetts Medical Society.

(Signed) ALFRED WORCESTER,
FREDERICK L. JACK,
HENRY JACKSON.

Dr. A. P. Merrill of Pittsfield reported for the delegation to the annual meeting of the Connecticut State Medical Society at Bridgeport, May 17 and 18, 1922. Both he and his fellow Delegate, Dr. G. L. Chase of Clinton,

were present at a meeting that they thought to be valuable and instructive. They commended the custom in the sister state of having reports from the secretaries of the district societies at the annual meeting of the Society; it made for rivalry and a keeping up of efficiency. Connecticut is aroused at present over the licensing of poorly trained practitioners by an elective board of licensure. Dr. George A. Moore of Brockton reported on his attendance at the annual meeting of the Rhode Island Medical Society at Providence, June 1, 1922. He read the program of the meeting and spoke of the custom of giving out a subject for original work for a prize for a year ahead. This year the subject was Radium Therapy. The meeting was most enjoyable and profitable.

Dr. W. P. Bowers offered the following motion, which was seconded and passed: *Moved*: That a committee of three be appointed by the Chair, the President to be the Chairman, to negotiate with the other medical societies of New England for the purpose of holding a combined meeting of all the New England medical societies at some time in the future.

The Chair nominated and the Council elected the following to fill vacancies in offices of the Society: E. J. Welch, Lowell, as Nominating Councilor for Middlesex North; C. F. Canedy, Greenfield, as censor for Franklin; J. D. Collins of Northampton, as censor for Hampshire; F. H. Lahey as censor for Suffolk.

The Secretary read a letter from the Maine Public Health Association to the President asking for a representative from the Massachusetts Medical Society to act in an advisory capacity to the Program Committee of the New England Conference on Tuberculosis, to be held at Poland Springs, September 28 to 30, 1922. The President nominated and the Council appointed Dr. Sumner H. Remick of Reading to this position.

Dr. W. T. Hopkins, in the absence of the Chairman, read a report of the Committee on Workmen's Compensation Act. The report was accepted and its recommendation, namely, that the Committee be discharged, was adopted. (See Appendix No. 7.) Dr. A. K. Stone made a verbal report for the Committee on Industrial Health Insurance. He said that in the absence of legislation the Committee had had no meetings. He advised that the Committee be discontinued, and it was so voted.

Dr. C. E. Mongan asked for authority to establish a Section of Obstetrics and Gynecology, under the terms of Chapter IV, Section 5 of the By-Laws. He moved, and it was seconded, that such a Section be formed, the selection of the Chairman and the Secretary

of the new Section to be left to the President, and it was so voted.

Dr. B. P. Croft of Greenfield presented the following resolutions at the instance of the Franklin District Society. They were seconded and carried.

RESOLUTIONS OF THE FRANKLIN DISTRICT MEDICAL SOCIETY.

Resolved, That the members of the Franklin District Medical Society, recognizing the great importance of closer contact of the District Societies with the parent body of the Massachusetts Medical Society through the medium of the Council, believe that such contact would be facilitated if the distance to the meeting place and the financial cost of reaching same were more equally distributed, and, therefore, we recommend that our Council members offer and support the following motions, provided that their subject matter has not already been acted upon, or that they are not unconstitutional:

1. That one or more of the Council meetings be held in Springfield, or Worcester.
2. That the expense of carfare of all Council members attending the Council meetings be paid from the treasury of the Massachusetts Medical Society.
3. That the Treasurer of the general Society prepare an estimate of the approximate cost of carrying out the purpose of this resolution, the basis of such estimate to be the average attendance at each annual meeting for the past three years, deducting the amount paid for mileage to supervising censors for attendance at their annual meetings.

Resolved, That previous to final action by the Council, a copy of this resolution be transmitted by the Secretary of the Massachusetts Medical Society to the Secretaries of all District Societies, with the request that its subject matter be acted upon at meetings of the respective societies, and the result of such action be communicated to the Council through the Secretary.

Dr. Mongan asked what is the meaning of "public health." He thought it confusing to the average practitioner to define the term, also what is a "public health nurse" and "what are her functions." He moved and it was voted that the definition of these terms be referred to the Committee on Public Health for a report at the next meeting.

The President read a letter from Mr. George R. Wakefield of Spencer concerning a permanent memorial to Dr. William T. G. Morton at Charlton, his birthplace, soliciting cooperation in raising funds. On motion the matter was referred to the Committee on Membership and Finance.

The names of the officers and orator nominated by the Nominating Committee were placed on the blackboard and on proceeding to ballot Dr. Croft stated that the following ticket received 87 votes and they were declared elected. While the balloting was in progress the President nominated and the Council appointed the following Standing Committees for the ensuing year:

OFFICERS OF THE MASSACHUSETTS MEDICAL SOCIETY. ELECTED BY THE COUNCIL, JUNE 13, 1922.

PRESIDENT: John W. Bartol, 3 Chestnut Street, Boston.

VICE-PRESIDENT: Charles E. Morrill, 24 Central Street, Somerville.

SECRETARY: Walter L. Burrage, 42 Eliot Street, Jamaica Plain.

TREASURER: Arthur K. Stone, Auburn Street, Framingham Center.

Librarian-Emeritus: Edwin H. Brigham, 5 The Fenway, Boston.

STANDING COMMITTEES FOR 1922-1923.

ELECTED BY THE COUNCIL, JUNE 13, 1922.

OF ARRANGEMENTS,

K. G. Percy, F. J. Callanan, Dwight O'Hara, J. C. Rock, L. S. McKittrick, W. T. S. Thorndike.

ON PUBLICATIONS AND SCIENTIFIC PAPERS.

E. W. Taylor, R. B. Osgood, F. T. Lord, R. M. Green, A. C. Getchell.

ON MEMBERSHIP AND FINANCE.

D. N. Blakely, A. Coolidge, Samuel Crowell, Gilman Osgood, Homer Gage.

ON ETHICS AND DISCIPLINE.

Henry Jackson, T. J. Robinson, David Cheever, F. W. Anthony, W. D. Ruston.

ON MEDICAL EDUCATION AND MEDICAL DIPLOMAS.

C. F. Painter, J. F. Burnham, A. G. Howard, R. L. DeNormandie, H. P. Stevens.

ON STATE AND NATIONAL LEGISLATION.

J. W. Bartol, E. H. Stevens, P. E. Jones, J. S. Stone, T. J. O'Brien.

ON PUBLIC HEALTH.

E. H. Bigelow, Annie L. Hamilton, E. F. Cody, Victor Safford, R. I. Lee.

COMMITTEE OF NINE, FOR THREE YEARS.

W. H. Robey, Jr., R. I. Lee, R. B. Osgood.

Adjourned at 2.25 P. M.

WALTER L. BURRAGE,
Secretary.

APPENDIX TO PROCEEDINGS OF THE COUNCIL.

APPENDIX NO. 1.

REPORT OF THE COMMITTEE ON PUBLIC HEALTH.

This Committee has met once a month throughout the year for the discussion of various methods of improving health conditions in Massachusetts.

The matter of holding a convocation in Worcester seemed well worth while, and the different ways of making such a convocation a success were studied in some detail, but the project was finally given up, as the great need seems rather to be that of the small towns. The Committee feels that the need of the doctors in these small towns is for some form of post-graduate work, to be carried on as near the locality of the country physician as possible. The various institutions, State and community hospitals, hospitals for the tuberculous, the feeble-minded, or the insane, might well be chosen for the place of meeting. Clinical material near at hand could then be made use of. Certain days might be chosen for clinic days, when a patient might be taken by his physician and several opinions obtained. In January, the work of the Committee to "Investigate Health Problems in Relation to the Sick in Rural Communities" was referred to the Public Health Committee. The conclusion of this Committee, after painstaking

investigation, seems to coincide with the above. A report, outlining a plan for financial expenditure to carry on the work, was published in the BOSTON MEDICAL AND SURGICAL JOURNAL, May 11, in part as follows:

"The Committee feels that a proper field agent could undoubtedly accomplish a great deal, directly and indirectly, for the advantage of the rural communities. The data collected by such a field agent would be of considerable service to the practitioners of the Massachusetts Medical Society, because there would be some means, perhaps, mainly through the BOSTON MEDICAL AND SURGICAL JOURNAL, for the interchange of valuable suggestions between isolated practitioners, who are meeting the same problems in presumably different fashions. The Committee feels that these data might be of great value in the establishment of some policies in regard to the rural communities which might have the support of the Medical Society. These policies would include, obviously, the problems of the encouragement of the establishment of small central hospitals according to the needs and the development and utilization of certain facilities, such as laboratory facilities for the benefit of the local practitioners, and thereby, of course, of the local communities. The Committee realizes that this is a very bare outline of a plan, but submits it for consideration. The Committee feels that the sum of \$5000.00 would be necessary for the payment and the expenses of a field agent, who would be capable of doing this work satisfactorily."

DEMONSTRATION OF THE SCHICK TEST.

At an early meeting the question of continuing the work of extending the knowledge of the Schick Test was discussed, and Dr. Joseph Garland was asked to carry the demonstrations to cities and towns in Eastern Massachusetts. It has been found that in some instances the technique of the Test was faulty, an incorrect reading resulting in some cases, and bringing discredit to this valuable method of deciding whether an individual is, or is not, immune to diphtheria. If properly done, and toxin antitoxin administered to the susceptible children, the morbidity of diphtheria should be as controllable as that of smallpox, with practically no mortality. Dr. Garland has been demonstrating this work for two years, His report since June, 1921, is as follows:

REPORT OF DR. JOSEPH GARLAND ON THE SCHICK TEST.

Following is the information you requested concerning my Schick activities. The 1921 Spring campaign ended on the last of May, so is not included in your current year. Starting December 22, 1921, and ending March 28, 1922, the following demonstrations were given: Framingham Hospital, Boston (physicians' children), Wakefield, Boston (Middlesex South Society), Deaconess Hospital, Concord; Anna Jaques Hospital, Newburyport; Clinton; Jordan Hospital, Plymouth; Heywood Memorial Hospital, Gardner; Massachusetts General Hospital Nurses' Alumnae Association. Figures furnished by the State Antitoxin Laboratory show the increase in output of toxin-antitoxin as follows:

June, 1921	661 c.c.
July	366 c.c.
August	272 c.c.
September	587 c.c.
October	1917 c.c.
November	2678 c.c.
December	3054 c.c.
January, 1922	8902 c.c.
February	3785 c.c.

It is to be trusted that our campaign had some influence in increasing these figures. Of course, it must be remembered that the State Department of Public Health has been very active during this period in furthering diphtheria prevention by these pro-

(Signed) J. GARLAND.

LECTURES ON PUBLIC HEALTH SUBJECTS.

The list of lecturers and their topics, as published frequently throughout the year in the *BOSTON MEDICAL AND SURGICAL JOURNAL*, has been of service to some of the District Societies. We gratefully acknowledge our indebtedness to the men who rendered this gratuitous service. The Committee is always glad to assist in making arrangements for lectures, if desired.

Respectfully submitted,

(Signed) ANNIE LEE HAMILTON, *Secretary*.

APPENDIX NO. 2.

REPORT OF COMMITTEE ON MEDICAL EDUCATION AND MEDICAL DIPLOMAS.

The Annual Report of this Committee divides itself into three subjects; first, assisting the Censors in determining the eligibility of candidates who would present themselves for examination for membership in the Society; second, report of the delegate sent by the Society to represent them at the Chicago meeting of the Council on Medical Education of the American Medical Association; third, sponsoring and endeavoring to promote legislation looking to the elevation of the standards required by the State Board of Registration in Medicine.

In respect to the first of these activities of the Committee, it has had about the usual amount of work to do. We have passed upon the eligibility of 14 candidates, permitting nine to come before the Censors and rejecting five. There has been little of interest in this connection except that the investigation of one candidate disclosed the fact that he was illegally practicing in this State, having failed to pass the State Board. The other matter was that of an osteopath who sought permission to take the Censors' examination and was rejected because he did not possess the degree of doctor of medicine, though in the opinion of some who knew him well, he is better equipped to practice than many who are "carrying on" in the full possession of all legal authorizations to do so. Personally my sympathy was with the candidate and he had no difficulty in procuring support from a distinguished group of practitioners in the district where he resides. There was nothing, however, to do, as our Society Rules provide for the awarding of the opportunity to come before the Censors for examination only to men who are regularly graduated from an acceptable medical school, and this he could not show.

The educational system under which we qualify to do business as professional men is so complicated that it is very difficult at times to "see the woods for the trees." All along the line injustice is being done, far more frequently than most of us know, because a matter has to be decided in accordance with a hard and fast rule from which there is no appeal to a body that is human and judicial and could weigh a case on its merits. This applies to the admission to and continuance in the medical schools of those whose preparation has, for one reason or another, been a little bit irregular. We speak of these things in this respect because we believe that the membership of this Society "by and

large" is not as conversant as they should be with respect to the requirements now being exacted of those who enter the medical schools; of the proportionate adjustment of the subjects required by the curriculum; of the methods of teaching now in vogue, and many other questions of vital importance to the maintenance of a standard of training which shall yield, first of all, a sound, sane body of general practitioners with, secondly, just enough specialists to attend to the particular circumstances which will arise in the experience of the larger group of general practitioners, requiring superb skill in treatment and occasionally in diagnosis; thirdly, this system of training will provide for those who are fitted and desire to qualify by special preparation for it, to enter positions in medical schools, either in high clinical professorships or in practical laboratory departments. We believe that the medical profession should be drawn more closely together than it now is, and that one way of doing this is by providing the means by which some of these fundamentals of medical practice should be kept before the profession as assiduously as the latest wrinkles in the toilette of the peritoneum are forced upon its attention. In whatever way this much-to-be desired end may be reached, it is certain to have a very beneficial influence upon the organization of the profession into a machine when necessary, to combat or promote legislation, hostile or favorable, as the case may be, to the interests of the medical profession and the public, where its health interests are involved. And it is this thought that is suggested by the third division of this report; viz., the medical educational interests of this Society as affected by legislation.

An intelligently awakened interest on the part of the profession in all matters which are the subject of legislative enactment is, we are convinced, the only way that results favorable to the interests of the schools, the public, and the profession may be secured. Before passing to the next subject, it should be said that a new list of acceptable medical colleges, revised to May, 1922, will soon be ready for distribution.

This year, as most of you know, the Committee introduced into the House "House Bill 955," which called for two years of pre-medical work, in addition to an acceptable four-year high school course, and specified the number of hours to be spent by the student in the study of the prescribed pre-medical subjects of Physics, Chemistry, Biology, a modern language and English, all of college grade. In addition, it was provided that he should, upon completing his course, spend one year as interne in a hospital of at least twenty-five beds. Two outstanding facts in regard to our efforts to secure this legislation are conspicuous. In the first place, we were not given "Leave to Withdraw," and a much emasculated bill, "House 1315," was enacted. It is the belief of most of the Committee of Public Health in the House and Senate that even under the old law, the Board of Registration had all the power it needed to control the licensing of practitioners at as high a grade as they chose to set. The bill as passed is an improvement on the old law in that it makes provision for a minimum educational requirement for matriculation in a medical school, the equivalent of a four-year high school course, and the board must examine in the science subjects required in the original bill to such an extent as to satisfy them that the candidate is sufficiently acquainted with these subjects. It is of course far from that for which we contended. The disadvantages of it from a practical point of view have been well pointed out by the Editor of the *BOSTON MEDICAL AND SURGICAL JOURNAL* in an editorial

appearing in a recent issue of that paper. In the second place, there has rarely been a Committee of Public Health in the General Court or a body of Legislators so systematically approached and made acquainted with the fact that the medical profession was really alive to a subject upon which they naturally have opinions. We are confident that by carrying out more thoroughly the methods employed in reaching the individual legislator that much more effective support may be secured for medical legislation in the future. I am going to speak plainly, for I believe the issues involved justify it. We are convinced that the little we did accomplish this year was due to the response which certain sections of the Society gave us through local concerted action. Somerville, Lowell, Newton, Abington, Springfield, Pittsfield, Newburyport, Northampton, and the physicians in the vicinity of these towns must be credited with bringing about a feeling in the Legislature that convinced that body that the medical profession was back of what was being asked for in the bill, and they did not this year throw it out of court. I regret to state that from scarcely any other section of the Commonwealth did we get any active support in our campaign. We asked for returns on the questions proposed and sent to every local branch of the Society.

Aside from those mentioned, we heard from none except Fall River and Greenfield, where there was an opinion adverse to the proposal of the Committee. This, of course, we are not criticising; on the contrary, we welcome it. What we do complain of is the negligence or unwillingness to coöperate in some way with those who are endeavoring to remedy a situation which is discreditable to the State of Massachusetts and its organized medical profession. Some machinery has been provided for bringing into action the enlightened professional opinion of the doctors of the Commonwealth. A more universal willingness to make use of this machinery is desirable, and when in the future it becomes necessary to marshal the influence of the medical profession on Beacon Hill, it is to be hoped that the Society will find an even more generous response than we received this year.

ROBERT L. DENORMANDIE.
HORACE P. STEVENS.

REPORT OF THE DELEGATE TO THE ANNUAL CONGRESS ON MEDICAL EDUCATION, CHICAGO, MARCH 6 TO 7, 1922.

The Congress began on Monday, March 6, at the Congress Hotel, Chicago, with a large attendance representing all parts of the United States and Canada. The meeting was opened by Dr. Arthur Dean Bevan, of Chicago, the President, who spoke on the necessity of a constructive program for medical education. He reviewed briefly the work of the Council on Medical Education for the past twenty years and quoted at length from a report of President Henry S. Pritchett in 1921, of the Carnegie Foundation. This report stressed the importance of the close inter-relationship of the medical school, the hospital and the dispensary, and described the ideal type of teaching hospital. Dr. Bevan also discussed the importance of the element of time in the construction of a medical curriculum, but showed that saving of time must not be at the expense of a rational premedical course, or of a year of hospital internship.

The next paper of the morning was by Dr. N. P.

Colwell, of Chicago, the Secretary of the Council, on "Problems Resulting from the Recent Improvements in Medical Education." This paper dealt with the increased cost of a medical education, the necessity for limiting the enrollment of students in the medical schools, the rapid turn towards specialization in the practice of medicine, the increased development in graduate clinics, the rapidly growing demand for hospitals and the increase in their number, the demand for interns, and the shortage of physicians in rural communities.

This paper was followed by a report on the undergraduate medical curriculum, "What Subjects if any, should be transferred to the Graduate Medical School," by Dr. Ray Lyman Wilbur of Palo Alto, Calif. After discussing the essential aims of undergraduate medical teaching, and something of the weakness of present methods, he explained his ideas in somewhat this form: 1. Push some clinical work as far back into the medical course as possible to heighten the interest of the student. 2. Divide up the last two years between general medicine and pediatrics, including the mental diseases, 40%; general surgery, 30%; obstetrics and general gynecology, 10%; hygiene and public health, 5-10%; optional work, 10-15%. 3. Bring the laboratories into closer conjunction with the clinics. 4. Have the clinician in his course cover subjects now handled by specialists, bringing the specialists in to help him; 5. Have more coördination in the courses to avoid duplication. 6. Make hospital experience with responsibility a requirement for graduation. 7. Keep the spirit of research alive all along the line in the medical course.

Dr. Hugh Cabot of Ann Arbor, Mich., read a report of the Committee on Education and Pedagogies, "A New Curriculum." This paper, after emphasizing the increasing tendency to rigidity in the present curriculum and showing how little opportunity there is for the student to progress according to his individual talents and ability, presented a new curriculum in tabular form in which the requirements, instead of being set down as so many hours for each subject, were put in the form of percentages giving a reasonable range for variation to meet individual needs.

Discussion was then thrown open on all the morning papers, including remarks by Dr. William Darrach of New York, Dr. E. P. Lyon of Minneapolis, Dr. David L. Edsall of Boston, Dr. Alexander Primrose of Toronto, Dr. H. Gideon Wells of Chicago, Dr. C. R. Bardeen of Madison, Wis., Dr. Alexander C. Abbott of Philadelphia, Dr. Nathaniel Allison of St. Louis, Dr. C. A. Hannon of Cleveland, Dr. Walter L. Biering of Des Moines, Dr. Charles P. Emerson of Indianapolis, Dr. Lewis B. Wilson of Rochester, Minn., Dr. Frank Billings of Chicago, Rev. C. B. Moultrie of Milwaukee, and Mr. Wallace Butterick, President of the General Education Board of New York. This discussion, approaching the subject from many different angles, was very interesting.

The afternoon session opened with a paper by Dr. C. P. Howard, of Iowa City, on "The Function of the Hospital in Medical Education." This paper dealt with the need of hospital beds for the teaching of the clinical branches, just as the dissecting room is required for the teaching of anatomy, and the laboratory for physiology. The clinical lecture has still, no doubt, a place in the curriculum, but its place is constantly growing less prominent in most of the modern medical schools. The writer stressed the importance of hospital instruction from the point of view of the student, and described what was being done at the University of Iowa, where, owing to state laws which provide for indigent adults and children, the University Hospital has been able to

expand from 125 beds in 1910 to 550 in 1922 without appreciably increasing the financial burden of the Medical School and University.

The next paper, by Dr. E. P. Lyon, of Minneapolis, described in detail the student internship system which has been put in practice at the University of Minnesota. This system is dependent upon a plan in practice during the past two years of dividing the school work into quarters. Half of the students from the class at the end of the sophomore year proceed straight ahead for six quarters without any long vacation. There is a vacation of four weeks in September. The other half takes two vacations of three months each, the regular amount. The first division, therefore, gets six months ahead. The result is that (1) about half of the students save six months in the medical course, (2) classes are graduated twice a year, in December and June, and (3) the hospitals have teaching twelve months of the year. In the first six months of the student internship there is a period of clerkship in which the student gets experience in the methods of examination, history writing, laboratory tests, etc. In the last six months of the senior year, there are only six lectures a week arranged on two afternoons. The rest of the work is elective. The student internship is the elective chosen by most of the class. As the University of Minnesota requires a hospital year following the four-year course for a degree of doctor of medicine, the student internship is so arranged to naturally lead up to the graduate internship which follows it. A questionnaire sent to students educated under this system showed, of 105, 99 had elected student internship and 6 took other electives of research in place of it. Of the 99, all but 3 in the light of subsequent experience would again choose student internship. Of the 6 who did not have student internship, 2 wished they had. The others mostly took research work.

Dr. L. S. Schmidt, of San Francisco, read a paper on "The Fifth Year Requirement as an Essential to Graduation." He went over the present requirements of existing medical schools and state laws in this regard and then described the system at the University of California, where the fifth year may be taken in any of the major departments of the Medical School or in any approved hospital or laboratory. If laboratory work is elected, it may be taken at any time after the first half year, provided the student has creditably completed his required work in the subject in which he desires to fulfil his fifth year requirement. The school has an arrangement with the Hooper Foundation for Medical Research, whereby he may take his laboratory work in that institution. In case hospital internship is chosen, the school provides blank forms which indicate the available internships and contain an agreement to accept the internship assigned and to remain throughout the period indicated. The hospitals to which interns are assigned must agree that each student shall be under the supervision of a member of the staff of the hospital and that the year's work must be under continuous approval by the medical board, and that the hospitals shall at all times conform to the requirements of the Council on Medical Education and Hospitals of the American Medical Association, and that reports shall be sent to the Dean's office quarterly and on exchange of service.

Dr. J. C. Litzberg, of Minneapolis, then read a paper on the experience at the University of Minnesota with the requirement of the intern year as a prerequisite for the degree of doctor of medicine. The system at Minnesota permits the student to select his own hospital as far as possible, provided that hospital meets with the requirements of the school. The school undertakes to guarantee internships and a committee secures enough places so

that all the students can be accommodated. The internship is looked upon as a contract on the part of the student to fulfil the requirements of the hospital, and on the part of the hospital to give the student as much instruction as is required by the school. The system has worked out very successfully.

Discussion of the afternoon papers was entered into by Dr. John M. Dodson of Chicago, Dr. Arthur D. Bevan of Chicago, Dr. Frank Billings of Chicago, Dr. George M. Kober of Washington, Dr. John A. Witherspoon of Nashville, Tenn., Dr. I. D. Metzger of Pittsburg, Dr. T. J. Crowe of Dallas, Texas.

The morning session of the second day, Tuesday, March 7, opened with a paper by Dr. Charles P. Emerson of Indianapolis on "Professors and Clinical Professors of Clinical Subjects." This was a study of what should be the proper qualifications for a real clinical professor. A thorough training in the premedical and preclinical sciences and approved ability as a laboratory research worker in at least one of these scientific subjects. But intellectual brilliancy and proved research ability, essential though they are, are not enough. They may be enough for a professor, but not for a clinical professor. The art of medicine is also necessary. This is possessed by some but not by all as a natural endowment which can be developed with experience. A third quality which the professor may not need, but which is just as necessary to the clinical professor is that sympathy for the sick patient, that love of fellow man which originally prompts him to dedicate all of his powers to the profession. Some preclinical teachers would seem to believe that clinical medicine is merely the application at the bedside of the preclinical sciences, and that the student who has mastered these sciences has covered a considerable portion of the field of medicine. While a man well trained in premedical sciences can gain for himself a much wider and firmer grasp of clinical medicine, there is no real overlapping of these two fields.

In the discussion of this paper, Dr. Alexander Primrose of Toronto described the scheme at the University of Toronto, where through a system of graded hospital services, both clinical and laboratory, promising men are trained with the idea of developing just such men as Dean Emerson has suggested in his paper.

The next paper by Dr. Hans Zinsser of New York was on "The Introduction of Public Health Information into the Undergraduate Medical Curriculum." There is an increasing demand for highly trained specialists in public health, a need which is being answered by schools of public health recently established. However successful the education of such leaders and specialists may be, the entire structure of organization for preventive measures will fail unless the practicing medical profession is alert to its obligations, and in this regard, capable of meeting them. While some lectures on public health administration problems, social service, quarantine, etc., may be necessary, the greater part of this work should be accomplished by the teachers in the other subjects of the curriculum, but should coordinate the teaching of public health in its relation to the subject which they cover. Thus, courses in bacteriology should cover the subject of immunology, and in the courses of clinical medicine the basic principles of social service and public health nursing should be included in the dispensary work and the principles of isolation, quarantine, epidemiologic information, etc., should be dealt with in teaching the care of infectious diseases.

Dr. Alexander C. Abbott of Philadelphia, Dr. David L. Edsall of Boston, Dr. John A. Ferrall of New York, Dr. John M. Dodson of Chicago, Dr. George M. Kober of Washington, Dr. John C. Fitzgerald of Toronto spoke in discussion of this paper.

The next paper, by Dr. J. T. McClintock, of Iowa City, was on "Teaching Facilities: Report of Com-

mittee on Equipment." This paper discussed the increased expense of building facilities, equipment and the needs of sufficient variation in the standard required to allow for reasonable changes in teaching methods, etc. He also spoke of the saving that could be effected by the avoidance of reduplication of laboratory and clinical equipment.

The paper was discussed by Dr. Henry Pate of Cincinnati.

The afternoon session opened with a paper on "The Cost of Medical Education to the Student," by Dr. Irving S. Cutter of Omaha. This paper was largely statistical and showed the results of a questionnaire sent to the students in each of the four medical years at the Universities of Indiana, Iowa, Maryland, Michigan, Nebraska, Syracuse and Virginia, and the Medical College of Virginia.

The next paper, on "Liberalization in Medical Education," was by Dr. A. C. Eycleshymer of Chicago. The products of medical schools may be considered as belonging to three principal groups—practitioners, investigators, and teachers. Lister, Pasteur, and Osler typify the groups. A few decades ago the country demanded and the schools furnished, for the most part, but one type of practitioner, and that type was the all round practitioner. The conditions of today are so different that the all round practitioner now would have been a specialist fifty years ago. The rural districts and small towns will be obliged to build and equip hospitals if they hope to obtain modern medical service. With the hospital goes the staff which in turn forms the basis of the group clinic. The rapid development of the group clinic is creating a situation which must be recognized by both the profession and the schools. One of the greatest needs in the medical schools today is the encouragement of students to devote their lives to the study of the causation and prevention of disease. How far can we organize research? We can help the young men to evince the spirit, but we cannot dominate him or restrain him. Those of us who come in contact with the men as they enter the medical schools are impressed by their differences in concept, habit and training. The fixed curriculum of half a century ago will not meet the conditions of today, yet in principle it has remained unchanged. The day is not far distant when schools must either incorporate in their curricula the particular requirements of each state board, or find that their graduates are not qualified to practice in some states. The one obvious solution is the creation of an elastic curriculum. It must be adjustable to instructional and clinical resources, it must anticipate the ever-changing conditions in the growth of medical science, and it must provide for collective teaching, cooperative study, individual study. We should determine as far as possible the special assets of each student at the time he enters the medical school and ever keep in mind his adaptability for certain kinds of work.

This paper was discussed by Dr. George M. Kober of Washington, Dr. William Keiller of Galveston, Tex., Dr. W. F. R. Phillips of Charlestown, S. C., and Dr. E. C. L. Miller of Richmond, Va.

H. P. SIEVENS, *Delegate*.

APPENDIX NO. 3.

REPORT OF THE COMMITTEE ON STATE AND NATIONAL LEGISLATION.

The Committee are indebted to outside agencies for help in two important matters.

No bills to abolish animal experimentation were introduced this year, in spite of the fact that an interstate convention of those opposed to animal experimentation was held in Boston. This result is largely due to the very able presentation of the

truth by Mr. Baynes and the others who worked with him.

The bill to establish a special board for the examination and registration of chiropractors was introduced, was assigned a hearing at a late date, March 6th, and then, at the request of the proponents, was put over to the next annual session.

The medical profession of the State of New York were so ably opposing a similar measure introduced in Albany that it apparently seemed wise for the chiropractors to put off their fight in this state. An able lobby cannot work satisfactorily in two states at once. The bill is merely postponed in this state.

Vaccination again came up for consideration in the form of two bills, one to abolish compulsory vaccination as a prerequisite to attendance in the public schools, the other favored by the Committee to extend compulsory vaccination to the private schools. A year ago the bill to abolish compulsory vaccination passed the Senate. This year both bills were defeated. The opposition to compulsory vaccination this year was of a different character from that of recent years. Less was said of the evils of vaccination and more stress was laid upon personal liberty.

In connection with vaccination and chiropractic measures, it may not be amiss to call attention to the numerous articles appearing in a magazine called "Physical Culture," opposing vaccination, favoring spinal adjustments, and proposing rather novel methods in the treatment of syphilis. The influences which control this publication may be guessed.

The enactment by Congress of the so-called Shepard-Towner act changed completely the aspects of the maternity aid question. The proposals made by the Special Commission in this state were not considered. The so-called Spencer bill—a poor relief measure—was given leave to withdraw by the Committee on Public Health, but was finally referred to the next annual session.

The bill for the acceptance of the provisions of the Shepard-Towner act was defeated. The question was then raised as to how much the state was being taxed for the distribution by Congress among the states of sums to be devoted to various purposes. The opinion of the attorney-general as to the constitutionality of the act was obtained and was unfavorable. The state is now to take steps to test before the Supreme Court of the United States the constitutionality of the act.

The bill introduced and most ably supported by the Committee on Medical Education and Medical Diplomas, which sought to raise the standards of medical education in Massachusetts, now among the lowest in the country, led to a slight gain. The bill provided that students should be fitted to undertake the study of medicine by two years of college work, or its equivalent, in those branches which lead up to medicine, and that the graduate should have a year's internship in a hospital before being entitled to registration as a physician.

As finally passed, the bill provided that the medical student must have graduated from a high school or its equivalent, and added to the requirements for registration to practice medicine, the ability to pass an examination in physics, chemistry, and biology. The real purpose of the proposed requirements, the preparation of the student to begin the study of medicine understandingly, was lost. One short step in advance has, however, been taken.

The bill for the registration of medical students for the limited practice of medicine was finally passed. This measure was deemed necessary by the Board of Registration in Medicine if methods of education now essential and working satisfactorily were to be continued under existing laws. Yet but one of the three Class A Medical Schools of Massachusetts deemed it necessary to send any representative to explain the simple provisions of the bill to

the Committees of the Legislature. The bill was narrowly saved from defeat.

The bill for registration of x-ray technicians was put over to the next annual session.

The bill for the establishment of a Division of Registration and Narcotic Drug Control in the Department of Civil Service and Registration was defeated.

The bill for the examination and registration of midwives was referred to the next annual session. It is a matter on which there is a wide divergence of opinion. All agree that the present conditions are unsatisfactory. Those who favor the bill look forward to a better education and recognition of midwives. Those who oppose it aim at their gradual elimination. It is a matter which at present concerns only certain of the larger cities with a considerable foreign population, but it is a matter upon which physicians should form opinions.

A bill to permit more than three members of any School of Medicine to serve on the Board of Registration was postponed to the next annual session.

An attempt to make a lawyer the Secretary of the Board of Registration in Medicine was defeated.

The proponents of a measure intended to defeat in part, at least, the purposes of the act passed a year ago for the physical examination of school children, were given leave to withdraw.

Bills to allow compensation in Industrial Accident cases for periods in excess of two weeks if this would aid in the restoration of the health of the injured workman, and doing away with the vague term, "unusual case," were defeated, as also were bills to allow compensation for other than strictly medical or surgical treatment.

Bills to provide a basis upon which medical fees in Industrial Accident cases should be approved, and relative to hearings upon the fees of physicians in these cases, were given leave to withdraw. The fees allowed for burial in Industrial Accident cases were, however, increased.

Among the bills whose proponents were given leave to withdraw were those regulating the sale of candy to children, requiring the physical examination of persons employed in hotels and restaurants, and for the appointment of doctors in small towns.

A year ago a bill was introduced which would have enabled any person owning property nearby to close any hospital. This year a more reasonable bill was introduced which was referred to the next annual session. It is maintained that conditions exist which make certain private hospitals objectionable to the neighbors. At present only lying-in hospitals and those caring for patients suffering from mental diseases are licensed. The question will undoubtedly soon come up for settlement as to what rights the neighbors have regarding the establishment of hospitals, and as to the licensing of all hospitals by the state.

Two acts dealing with tuberculous cattle have been passed. One aims to prevent the transfer of infected cows, the other aims at the eradication of disease by providing for compensation to the owners of cattle slaughtered because of infection. Both of these measures are of importance because they will help to prevent tuberculosis among children.

The Department of Public Health was directed to report on the possibility of establishing hospitals for the treatment of surgical or non-pulmonary tuberculosis.

Within a few days the Department of Public Health has been directed to investigate the entire subject of tuberculosis in the Commonwealth, including the matter of state, county and municipal tuberculosis hospitals or hospital districts, ascertain the cost and maintenance cost of said hospitals; investigate the valuations of said property in detail and report as to the advisability of the Commonwealth taking over and maintaining these tuberculosis hos-

pitals, together with an estimate of the cost involved. The Department also shall report what, in its opinion, should be the general policy to be pursued by the Commonwealth, both as to methods of treatment and distribution of expense thereof in relation to the entire subject of tuberculosis in any state, county or municipal hospital, or hospital district. The report is to be made next January.

The proposal to change the name of the Department of Mental Diseases to the Department of Mental Health has been put off.

The plan to establish a Division of Mental Hygiene within the Department has been put off.

The plan to have those indicted for crimes of a capital nature or indicted more than once for crime examined by the Department of Mental Diseases to determine their mental conditions was defeated. This bill would have done much to simplify legal procedure because the report of the Department would have been unprejudiced evidence before the Court.

Definite steps in advance have been taken to make the illicit dealing in narcotic drugs more difficult, and to permit more adequate care of the drug addicts throughout the state.

A matter brought up by Dr. S. B. Woodward February 2, 1921, and referred to the Committee by the Council, dealing with the limit set to the funds which the Society may hold, has been acted upon by the passage of the following vote:

To recommend that action be taken looking toward a petition to the next General Court for the enactment of a statute amending Chapter 15, Section 9, of the Statutes of 1921, relating to funds; and, if approved by the Society at its annual meeting, a committee be appointed, consisting of the President and Secretary, who, in consultation with legal counsel of the Society, shall prepare a bill to be submitted for the approval of the Council at its stated meeting in October, 1922.

Respectfully submitted,

JAMES S. STONE, *Secretary*.

APPENDIX NO. 4.

REPORT OF THE CERTIFIED ACCOUNTANT AS TO THE FINANCIAL SITUATION OF THE JOURNAL FOR NINE MONTHS, UP TO DECEMBER 31, 1921.

BOSTON MEDICAL AND SURGICAL JOURNAL,
126 Massachusetts Avenue,
Boston, Mass.

Gentlemen: In accordance with your request, I have audited the books of the BOSTON MEDICAL AND SURGICAL JOURNAL for the period from April 1, 1921, to December 31, 1921, and submit herewith:—

Schedule A. Statement showing the Assets and Liabilities of the BOSTON MEDICAL AND SURGICAL JOURNAL, December 31, 1921.

Schedule B. Statement showing the Profit and Loss Account of the BOSTON MEDICAL AND SURGICAL JOURNAL, from April 1, 1921, to December 31, 1921.

CASH.

All cash receipts and disbursements have been verified. The bank account has been reconciled and found to be in agreement with the books.

ACCOUNTS RECEIVABLE.

The various items shown under Accounts Receivable on Schedule A represent the amount due customers on account of advertising, reprints, etc.

SUSPENSE ACCOUNT.

This account represents bad accounts which have been turned over to a collection agency and which are temporarily carried in this account.

OLD JOURNALS.

The balance of this account represents the estimated cost of all old journals on hand December 31, 1921.

ACCOUNTS PAYABLE.

A separate exhibit is submitted giving the detail of the amounts owed by the JOURNAL on December 31, 1921, the largest being due for printing.

SURPLUS.

Considerable difficulty was experienced in obtaining the correct figures for the Surplus Account as of April 1, 1921, inasmuch as the books were started in October, 1920, and had continued without being closed through December 31, 1921. In order to prepare financial statements for the period from April 1, 1921, to December 31, 1921, it was necessary to make a great many adjustments in order to arrive at the balances on April 1st.

Contributions made by the Massachusetts Medical Society have been added to the balance of April 1st, and the net loss from operations deducted, showing a net Surplus on December 31, 1921, of \$5533.70.

PROFIT AND LOSS ACCOUNT.

In preparing the Profit and Loss Account as shown on Schedule B, I have shown the revenue from all sources from which the expenses have been deducted, leaving a net operating loss of \$9617.24. This operating loss represents the actual net loss without taking into consideration any contributions made by the Massachusetts Medical Society.

SALARY OF EDITOR.

The \$1500.00 turned over to the JOURNAL by the Massachusetts Medical Society for the payment of the editor's salary was not received until after the close of the year, although I have caused it to be brought on the books as of December 31, 1921. As shown in the statement of revenue, the contribution of \$1500.00 represents the \$1500.00 salary paid to Dr. Bowers, who in turn contributed it to the JOURNAL.

GENERAL.

A new ledger has been opened as of January 1, 1922, containing revenue and expense accounts which will facilitate an audit during the coming year, and will at all times enable you to prepare a statement showing the Assets and Liabilities, or a statement showing the revenue and expenses for any period without the necessity of analyzing the accounts as done during the past year.

Respectfully submitted.

HORACE C. HAETSHORN,

Certified Public Accountant.

APPENDIX NO. 5.

REPORT OF THE COMMITTEE ON MATERNAL AND
INFANT WELFARE.

The Committee made two reports to the Council last year, one approved by the whole Committee, and the other a minority addendum. These reports showed that there were differences of opinion relating to the questions connected with maternal and infant welfare work.

During the past year much time has been devoted to discussions relating to the functions of the Committee and suggestions for plans which might lead to constructive action. Some of the Committee felt that valuable information would be obtained by a survey of those hospitals in this State that are doing obstetric work, but this did not meet with unanimous approval.

The Committee did agree to engage in a study of maternal deaths as reported to the Department of Vital Statistics on record at the State House, and that letters should be sent to those physicians who had reported deaths under the classification of maternal deaths, for the purpose of ascertaining the circumstances surrounding these cases and any etiologic factors involved. With these objects in view, a clerk has been employed to tabulate cases of maternal deaths, as shown by the State reports.

Considerable delay was imposed by the request of the registrar of vital statistics for postponement of a study of these cases until such time as the records could be examined without inconvenience to those in charge at the State House. Some copies of the death returns have been submitted and about one hundred letters to physicians have been sent. The responses have not been in sufficient numbers to warrant definite conclusions at this time, but are encouraging because of the spirit of coöperation shown.

The Committee regards the investigations already undertaken as of value and feels that they should be carried further. Therefore, the Committee submits this report as a report of progress and recommends that the Committee be continued.

For the Committee,

WALTER P. BOWERS,

[All members of the Committee have signified approval of the report.]

APPENDIX NO. 6

REPORT OF THE COMMITTEE ON CANCER.

The Committee on Cancer has been active during the past year. The principal work carried out has been in connection with the organization of "Cancer Week" in Massachusetts, as a part of the national

"Cancer Week," from October 30th to November 5th, 1921. This campaign, in charge of the Massachusetts Committee of the American Society for the Control of Cancer, was aided by your Committee in two ways. First, members of your Committee took an active part in the organization and direction of this campaign; second, it invited coöperation on the part of district medical societies throughout the State. The educational results obtained through public and professional lectures, distribution of literature, and the public press have been highly encouraging. A summary of the work accomplished during the "Cancer Week" has been published in the *Boston Medical and Surgical Journal* for March 9, 1922, and needs not to be described here. It is felt that the results obtained should be driven home by a second "Cancer Week" occurring next autumn, and plans for this end are already under way. The experience gained during the "Cancer Week" last year should prove highly valuable in bringing out a broader and more effective educational campaign. We feel that a Committee on Cancer of the Massachusetts Medical Society has been of use in connection with this work and that such a committee should be continued.

Very respectfully,

EDW. REYNOLDS, *Chairman.*

APPENDIX NO. 7.

REPORT OF THE COMMITTEE ON WORKMEN'S
COMPENSATION ACT.

This year something over thirty-seven bills were filed with the Legislature dealing with various problems of workmen's compensation. Directly upon these bills having been filed, your Committee held several meetings which were fairly attended, and took up all the bills of this nature for consideration. After considerable discussion, it was decided that eight of the bills were such as to need the support of the two medical societies.

Perhaps the most important bill was Senate No. 270, which aimed to remove the ambiguity of the present law by substituting for the word "unusual" the words "in all cases where medical treatment will minimize the disability or aid in the restoration of the injured to working capacity for a longer period in the discretion of the Industrial Accident Board."

Another vitally important bill was Senate No. 250, which added to the present law after the words, "personal injury," the words "or disease," amplifying the law so as to include occupational diseases.

House No. 368 was considered important as providing for massage, baking, electric, and other treatment, in the cases needing it.

Senate No. 271 clarified the law by providing that any decision of the Industrial Accident Board which may now be rendered by one member only of the Board should be subject to review by the entire Board.

Senate No. 272 defined more clearly that the fees paid the physicians in connection with these cases should be based upon the allowance of not less than the average minimum fee in the locality or district in which the service is rendered; and further provided that where the department was of the opinion that an artificial eye or limb or other mechanical appliance would promote his restoration to industry, it might so order it.

House Bill No. 680, providing that no physician should be employed as an impartial who had been employed by any insurance company during the previous two years, your Committee decided to oppose as being far too indefinite.

After several meetings of your Committee, a joint meeting was held with the Committee on State and

National Legislation, at which the President and Dr. J. S. Stone were present, giving valuable suggestions and advice.

Upon receiving notice of the dates for the hearings on these bills by the Joint Judiciary Committee, your chairman was present and presented the views of the two societies in relation to these bills on three successive days. In passing, it may be said that all of these bills which we approved were filed with the one purpose of clarifying the present law and endeavoring to protect all those concerned against the marked tendency on the part of the Supreme Court, as evidenced by its decisions in recent years, to narrow application of the law. The changes suggested were believed to be enormously important to the better and more effective working of the law, and we feel sure these bills had the approval of those of the Industrial Accident Board who were best in position to know the details in connection with them. In addition to your chairman, a few others representing different organizations throughout the State were present and spoke in support of the bills. There was no opposition at any of the hearings, and yet the Joint Judiciary Committee reported essentially on all of them, "Leave to withdraw," and no further action has since been taken by the Legislature on any of the bills.

Your chairman feels that at present, with the insurance interests as thoroughly well organized as they are, it is a great question whether such time as was spent on these bills was worth while. It is certain that the combined societies can accomplish no change in the law without extraordinary activity, a widespread interest, and energetic work by a large number of men throughout the State. He would suggest that the Committee be discharged, and that we await a sufficiently important crisis in matters relating to workmen's compensation to awaken enthusiastic interest on the part of the fellows of the societies, and then form a new committee to meet the exigency.

ARTHUR N. BROUGHTON, *Chairman*.

Abstract.

NATIONAL TUBERCULOSIS ASSOCIATION MEDICAL RESEARCH.

X-RAY AND CLINICAL FINDINGS IN NORMAL CHEST OF CHILDREN, 6 TO 10 YEARS.

THE above is the title of a report recently handed in by a committee appointed by the National Tuberculosis Association to investigate and report on the x-ray and clinical findings in the normal chest of children 6 to 10 years. This committee was composed of three clinicians, Drs. H. R. M. Landis of the University of Pennsylvania, Charles R. Austrian of the University of Johns Hopkins, and K. D. Blackfan of the University of Cincinnati, and of three roentgenologists, Drs. H. K. Pancoast of the University of Pennsylvania, F. H. Baetjer of the University of Johns Hopkins, and H. K. Dunham of the University of Cincinnati. This committee has been at work during the past two years and has only recently handed in its report.

The conclusions arrived at in such a subject as this of necessity cannot be absolutely definite one way or the other, but these conclusions are none the less of the greatest of value. There is probably no subject at the present time concerning which there is more difference of opinion among both clinicians and roentgenologists, and especially between the clinician and the roentgenologist, as in the diagnosis of bronchial gland tuberculosis and as to what consists the normal and what the abnormal in the child's chest and the causes thereof.

Clinical data dealt with in this report were obtained by careful examination of apparently healthy children between the ages of 6 and 10 years. All children who showed signs of disease were excluded. Children from various strata of society, foreign and native-born, residents of urban and of rural communities, school children and children residing in institutions, children exposed to tuberculosis and some without a history of such exposure, children with and without a history of previous infectious diseases, all symptom-free, and of an approximately normal height and weight for their ages, were studied. A tuberculin test was made on every child. The clinical data were then assembled, and after the roentgenologist had interpreted his plate independently, the clinical and roentgenographic findings were correlated. In all, 500 children were thus studied.

Among other conclusions they believe that a just detectable diminution of resonance over the apical regions is of no significance unless associated with a modification of the breath sounds in those areas or with other abnormal auscultatory findings. The so-called puerile breathing, breath sounds of a harsh, sharp character, with expiration longer and better heard in the child, is physiological and often incorrectly interpreted as evidence of pulmonary disease. Often, however, the so-called vesicular respiratory murmur, characteristically present in adult life, is heard. They claim that d'Espine's sign as indicative of enlarged tracheo-bronchial lymph nodes is, to say the least, of doubtful value. In 23 of the children this sign was present without x-ray or any other evidence of mediastinal mass. Eustace-Smith's sign is so generally present that it is of little or no diagnostic worth. The presence of these two signs together with impairment of resonance in the interseapular region is all too frequently made the premises for a diagnosis of tuberculosis of tracheo-bronchial lymph nodes. This they believe to be unwarranted. They emphasize the importance of acute sudden infections as the cause of enlargement of the bronchial glands, such

as measles, whooping-cough or tonsillar infections.

The clinicians on this committee, Drs. Landis, Austrian and Blackfan, present the following conclusions:

1. The data obtained on percussion and auscultation of the lungs of normal children show wide variations from a fixed standard. These variations are usual and are considered to be within normal limits.

2. Inasmuch as the changes referred to are dependent often upon alterations that persist as the residua of past infections of the respiratory tract, it is obvious that a careful anamnesis, with special reference to all infections, is necessary if diagnostic errors are to be avoided. Even a history carefully taken is often unreliable, as minimal infections are soon forgotten by many and among the unintelligent classes even more significant indispositions are not readily recalled.

3. Failure properly to evaluate these deviations from a fixed standard will often lead to the unwarranted diagnosis of disease and to even less justifiable treatment.

4. With a proper appreciation of the widest variations that the normal may present from the ideal, the informed clinician is better able correctly to understand the findings of the roentgenologist, and each, coöperating with the other, is less liable to error.

5. D'Espine's sign as indicative of enlarged tracheo-bronchial lymph nodes is of little value.

6. Recognition of and familiarity with the foregoing data is of cardinal and practical importance to every patient, potential and established. Without a proper appreciation of the facts set forth, no intelligent differentiation between a normal and an abnormal respiratory tract can be made.

The three roentgenologists, Drs. Pancoast, Baetjer, and Dunham, summarize their opinions as follows:

The Normal Chest.—The normal chest of the child, from the roentgenologic standpoint, is subject to such wide variations within normal limits as to be beyond the possibility of exact description.

Hilum Shadow.—The conglomerate shadow commonly called the hilum shadow, when found lying entirely within the inner third or zone of the lung area, can be disregarded (or regarded as normal), except where it is made up of a solid mass of homogeneous shadow giving undoubted evidence that it represents a growth or mediastinal pleurisy.

Calcified Nodes.—Calcified nodes at the root of the lung, without evidence of lung disease, are of no significance except as a possible evidence of some healed inflammatory condition, possibly but not necessarily tuberculous. They are a common finding in normal chests.

Density and Thickness of Trunk Shadows.—

In the normal lung the bronchial trunk shadows are not visible in the extreme apical regions. For convenience of description the remainder of the lung is divided into three vertical zones, extending outward from the lateral border of the spinal shadow to the lateral chest border. The inner zone contains the root shadows. The mid-zone contains the trunk shadows, gradually fading out into their final subdivisions. The peripheral zone contains radiating lines from these and fading off before the periphery is reached. Where in the mid-zone or peripheral zone these shadows do not disappear in the characteristic fashion described, the appearance may be evidence of a variety of conditions, past or present, of an inflammatory nature or otherwise. It may accompany a tuberculous process but is not necessarily indicative of tuberculosis.

Improper or Misleading Terms.—The use of the terms "peribronchial tuberculosis" and "parenchymal tuberculosis" is not to be recommended in the interpretation of roentgenograms of the chest. Until corroborated by laboratory or clinical findings, the use of the terms "active" and "quiescent" should not be definitely applied to evident lesions demonstrated on plates.

UNITED STATES CIVIL SERVICE EXAMINATION.

JUNIOR MICROANALYST, AUGUST 9, 1922.

The United States Civil Service Commission announces an open competitive examination for junior microanalyst on August 9, 1922, at any of the places listed in the official notice at which examination is requested in applications received in time to mail examination papers. Vacancies in the Bureau of Chemistry, Department of Agriculture, for duty in Washington, D. C., and in the field, at \$1400 to \$1800 a year, and in positions requiring similar qualifications, at these or higher or lower salaries, will be filled from this examination, unless it is found in the interest of the service to fill any vacancy by reinstatement, transfer, or promotion.

The examination referred to will be given on the date mentioned therein at the places named in the official notice. A request for examination on another date or at a place not included in the list cannot be granted. Except where otherwise indicated, application blanks may be obtained from the local secretary of the United States Civil Service Board at the postoffice.

BOOKS RECEIVED FOR REVIEW.

Upon written request, authors will be furnished free one hundred eight-page reprints, without covers, or the equivalent in pages in articles of greater length.

The Journal does not hold itself responsible for statements made by any contributor.

Communications should be addressed to The Boston Medical and Surgical Journal, 126 Massachusetts Ave., Boston, Mass.

REPORT OF THE COMMITTEE FOR THE STUDY OF NURSING EDUCATION.

THIS committee has published its report under date of June 27, 1922. As constituted at present the committee consists of the following named persons: C. E. A. Winslow, Dr. P. H., chairman, Yale Medical School, New Haven; Mary Beard, R.N., Boston; H. M. Biggs, M.D., New York; S. Lillian Clayton, R.N., Philadelphia; Lewis A. Conner, M.D., New York; David L. Edsall, M.D., Boston; Livingston Farrand, M.D., Ithaca; Annie W. Goodrich, R.N., New York; L. Emmett Holt, M.D., New York; Julia C. Lathrop, Washington, D. C.; Mrs. John Lowman, Cleveland; M. Adelaide Nutting, R.N., New York; C. G. Parnall, M.D., Ann Arbor; Thomas W. Salmon, M.D., New York; Winford H. Smith, M.D., Baltimore; E. G. Stillman, M.D., New York; Lillian D. Wald, R.N., New York; W. H. Welch, M.D., Baltimore; Helen Wood, R.N., St. Louis; Josephine Goldmark, Secretary, 270 West 94th Street, New York City.

The plan agreed upon as set forth in their report provides for nursing service embracing three grades:

(1) The trained registered nurse for the care of the acutely ill, the present training course of three years to be enriched and im-

proved and at the same time reduced 20 per cent. in length, without lowering standards;

(2) the public health nurse, the supervising nurse, and the teacher in schools of nursing, who are to receive specialized postgraduate training in addition to the standard course for registered nurses; and

(3) the subsidiary nursing worker, to be trained by an eight or nine months' course and licensed as nursing aide or nursing attendant for the care of minor and chronic illness and convalescence.

Throughout the report emphasis is laid on the fundamental necessity of generous financial support—which has never yet been provided—for all forms of nursing education.

The committee gives a clear conception of the rôle of the Public Health Nurse which may be an answer to the question, what constitutes a Public Health Nurse?, which has been asked frequently of late, in the following language:

The function of the nurse in public health is explained as follows:

"The new educational objectives of the health administrator may be approached to a limited extent by mass methods. The printed page, the public lecture, the exhibit, the cinematograph, the radiogram, help to prepare the ground and make success easier. The ultimate victory over ignorance is, however, rarely attained in such ways. Direct personal contact with the conditions of the individual life is essential to success in a matter so truly personal as hygiene. We have sought during the past twenty years for a missionary to carry the message of health into each individual home; and in America we have found this messenger of health in the public health nurse. In order to meet generally accepted standards we should have approximately 50,000 public health nurses to serve the population of the United States, as against the 11,000 now in the field. All public health authorities will probably agree that the need for nurses is the largest outstanding problem before the health administrator of the present day."

The Committee emphasizes the supreme value of combining bedside and instructive public health nursing and holds that the nurse who renders direct professional service in lessening the burden of illness "has an overwhelming advantage then and thereafter in teaching the lessons of hygiene."

As to her training, it is the judgment of the Committee that the public health nurse, as a "teacher of hygiene in the home,"

"should be equipped with no less rigorous training than that accorded to the bedside nurse, further supplemented by special studies along lines of public health and social service."

In referring to the alleged shortage of nurses the Committee reports that in the period 1910 to 1920 there has been recorded an increase of 83 per cent. in the number of trained registered nurses so that the problem is one of distribution rather than an actual shortage, because the majority of trained nurses are concentrated in the larger cities and the shortage in smaller places is due to economic factors rather than to inadequate numbers.

The Committee emphatically opposes all schemes which have been advanced which would provide for shorter training courses and lowered standards, but since there are more than half of the 300,000 male and female nurses in the United States in the substandard class the conclusion is reached "That steps should be taken through state legislation for the definition and licensure of a subsidiary grade of nursing service, the subsidiary type of worker to serve under practicing physicians in the care of mild and chronic illness, and convalescence, and possibly to assist under the direction of the trained nurse in certain phases of hospital and visiting nursing."

The Committee has reached the conclusion that while a subsidiary grade of nursing service is desirable and inevitable, the grade of nurse to be employed for any case should be determined not by the economic status of the patient but by the nature of the illness. "For the care of acute and serious illness and for public health work it seems certain that we need high natural qualifications and sound technical education; for the care of mild and chronic illness and convalescence it may well be that a different type of capacity and training may be necessary."

For this substandard nurse the Committee offers the suggestion that for some people who would be burdened by the expense of this service the cost should be met by "some form of community organization or along lines of group insurance."

In analyzing the conditions in hospital training schools for nurses the practice employed in twenty-three carefully selected schools were carefully studied and the conclusions reached are that "defects were found in both the practical ward training and in the class-room teaching. "Inadequate laboratory equipment," "excessive night work," "inad-

equate supervision" of student nurses, and "lack of an intelligently planned progressive" course of study are among the points mentioned for criticism. "Most striking of all," however, according to the Committee's report, "was the factor of time wasted in procedures essential to the conduct of the hospital, but of no educational value to the student concerned," and the criticism is offered that one fourth to one fifth of the students' time is wasted on details of no practical value.

The concrete suggestions relating to the teaching of nurses presented by the Committee are, first, that adequate funds should be available for the expenses of the school; second, that student nurses should be replaced by graduate nurses in the execution of routine duties; third, that the pre-nursing educational requirements should be at least a high school course or its equivalent; and, fifth, a reduction of the time of training to twenty-eight months and the day's work to eight hours.

In order to provide for the subsidiary grade of nurses it is advised that courses should be established in "special hospitals, in small unaffiliated general hospitals or a separate section of hospitals where nurses are also trained." This latter term of training to be of eight or nine months' duration "provided that the standards of such schools are approved by the same educational board which governs nursing training schools."

The University School of Nursing is strongly recommended for the development of well equipped instructors in schools of nursing. Such schools should be a separate and independent department of the university, much like the present medical school. Since the training of nursing aides, of nurses and of teachers costs money a campaign should be conducted to secure adequate funds. The report closes with the following statement:

"If the community needs and desires the service of competent nurses for the care of the sick and the prosecution of the campaign of public health, it must pay for their education, as it pays for every other conceivable kind of education—either through taxes or through the generosity of its great philanthropic foundations."

This report, as a whole, is an admirable piece of work and sets forth a constructive policy which, if followed, would be ideal so far as human agents can carry into effect the recommendations of wise advisers. The great difficulties will be found in the inability of the great number of small hospitals to conform to these requirements. Fortunately or unfortu-

nately, a great deal of medical service is rendered in small hospitals which are serving communities unable or unwilling to contribute much more in the way of financial support. Many of these hospitals are ambitious to maintain training schools, some because it is felt that the human material should be utilized for teaching purposes and others solely because the training school furnishes cheap nursing service. One can logically criticize the small hospital training school in comparison with the large, well equipped institutions in many instances, but we must acknowledge that the average quality of medical and nursing service is better in those communities in which the hospital functions as the central agency by and through which the medical profession receives inspiration and renders service. The nurse, although she may not always compare favorably with her sister in the large metropolitan hospital, may be doing much good as the physician's coadjutor.

The ideals of the Council on Medical Education may, it is feared, have exerted a blighting influence on some of the small but honorable medical schools. The question of how far the requirements for higher nursing standards should be applied is a serious one, and although improvements are most desirable, the problem should be considered in all its aspects. If there is danger of seriously inhibiting the usefulness of small hospitals, drastic changes in standards should be adopted only because the greater good to the greater number warrants such alterations.

NEWS ITEMS.

WEEK'S DEATH RATE IN BOSTON.—During the week ending June 24, 1922, the number of deaths reported was 163, against 204 last year, with a rate of 11.13, against 14.04 last year. There were 23 deaths under one year of age, against 24 last year.

The number of cases of principal reportable diseases were: Diphtheria, 46; scarlet fever, 28; measles, 145; whooping cough, 13; typhoid fever, 3; tuberculosis, 48. Included in the above were the following cases of non-residents: Diphtheria, 3; scarlet fever, 6; measles, 1; typhoid fever, 1; tuberculosis, 6.

Total deaths from these diseases were: Scarlet fever, 1; tuberculosis, 20. Included in the above were the following cases of non-residents: Tuberculosis, 2.

WELLESLEY COLLEGE RESEARCH FELLOWSHIP.—A research fellowship of \$1000 for the study

of orthopedies in relation to hygiene and physical education will be offered by Wellesley College beginning in September, 1922, and continuing for one year.—*Science*, June 23, 1922.

ADDITIONAL FUNDS FOR TREATMENT OF LEPROSY.—The sum of \$650,000 would be appropriated by Senate Bill 3665 to enable the Secretary of the Treasury, through the United States Public Health Service, to provide care and treatment for persons afflicted with leprosy. The money, should the bill become a law, would be used in improving the government leprosarium at Carville, Louisiana, and also for the transportation and care of patients at that institution, as well as for the prevention of the spread of leprosy in the United States.

DEPARTMENT OF PHARMACOLOGY, HARVARD MEDICAL SCHOOL.—During the exercises of the Annual Meeting of the Massachusetts Medical Society, over 175 fellows attended the exercises conducted by this department, showing that there is interest in the treatment of diseases by medicinal agents.

ADDRESS BY DR. W. B. CANNON.—Dr. Walter B. Cannon will give an address on "What Has Been Accomplished by Animal Experimentation" during the meetings of the Pacific Northwest Medical Association, July 6, 7 and 8.

RED CROSS NURSES.—In Wisconsin over 100 farms were partially destroyed and many others rendered a total loss in June. Working with a mobilized citizens' committee were two Red Cross nurses assisting in the care of the injured and the sick. In June, also, Red Cross nurses were called upon to serve in the emergency created by the Iververne, L. L. fire, where there were many casualties.

Miscellany.

LEGISLATIVE MATTERS.

A REVIEW OF NATIONAL LEGISLATION CONCERNING NURSES.

ALL legislation pertaining to public health is, obviously, of interest to nurses and public health nurses. The 67th Congress has had before it, however, a number of bills which directly concern the members of the nursing profession. Perhaps the two most important are the Wadsworth-McKenzie pay bill (H. R.

10972) and the Lehlbach-Sterling reclassification bill (H. R. 8928).

The Wadsworth-McKenzie bill is designed to readjust the pay and allowances of the Army, Navy, Marine Corps, Coast Guard, Coast and Geodetic Survey, and Public Health Service. It passed the House on May 12 and the Senate on May 22, was considered in conference, agreed upon, and signed by the President. The act went into effect on July 1.

Section 13 of the act provides the following annual rates of pay for Army and Navy nurses (members of the Nurse Corps of the Public Health Service are not affected by this act): First three years' service, \$840; second three years' service, \$1080; third three years' service, \$1380; from tenth year on, \$1560.

In addition to their pay as nurses, superintendents of nurses receive a money allowance of \$250 a year; assistant superintendents, directors and assistant directors, \$1500 a year; and chief nurses, \$600 a year. Nurses are also allowed subsistence (60 cents a day) and an allowance for rental (\$20 a month), the same as certain officers.

The Lehlbach-Sterling bill provides for reclassification of all civilian government employees. The bill passed the House on December 15, 1921, and was reported in the Senate on February 3, 1922, with several important amendments, some of which directly concerned nurses. In the bill as originally drawn, nurses were included with housekeepers under the Institutional Service. The Senate eliminated this service entirely and placed nursing in the Professional and Scientific, and Subprofessional services. In the former service there are six grades, with compensation ranging from \$1800 a year to \$7200, depending upon the type of work performed, the amount of responsibility, and other factors. Salaries in the Subprofessional Service are from \$1020 to \$3180 a year, divided into six grades. The nurses of the Public Health Service would be governed by this salary schedule.

Several pension bills, which are pending, contain provisions relating to nurses. The bill H. R. 4, which passed the House on February 1, 1922, and has been reported in the Senate, provides for a pension of \$20 a month to all women who served as nurses for 90 days or more during the War with Spain, the Philippine Insurrection, or the Chinese Boxer Rebellion. A bill (S. 3629) has also been introduced to give a similar pension to nurses supplied by the American Red Cross to the Army for 30 days or more during the War with Spain. Another pension bill (H. R. 10031) would give \$50 a month to nurses who served in the Civil War. No action has been taken on these last two bills.

CERTIFICATES OF REGISTRATION REVOKED.

At a meeting of the Board of Registration in Medicine held June 21st, 1922, the certificate of Philip A. E. Sheppard was revoked. The Board interpreted Dr. Sheppard's professional relations with a patient who applied to him for treatment as constituting "unprofessional conduct," for, by the method outlined in the JOURNAL recently, a diagnosis of sarcoma and syphilis had been made and, according to the belief of the Board, based on the testimony submitted, a promise of certain cure was given provided the patient would report for treatment five days each week for several months at a cost of five dollars per treatment, with a total cost of from five hundred to one thousand dollars.

The certificate of Alfred J. Boyle of Boston was revoked for alleged violation of the narcotic drug laws.

The following certificates were suspended: Neshan F. Barronian for six months for associating himself with an unregistered person for the purpose of carrying on the practice of medicine.

Patrick V. Brunick, for fifteen days, for associating himself with an unregistered person, and the certificate of Abram R. Goodman for fifteen days for unprofessional conduct as shown by his testimony before the Industrial Accident Board and confirmatory testimony of 24 other witnesses.

THE MASSACHUSETTS ASSOCIATION OF ASSISTANT PHYSICIANS.

THE 55th meeting of the Massachusetts Association of Assistant Physicians of the Department of Mental Diseases was held at the Monson State Hospital, Palmer, Mass., on Friday, June 16, 1922. Forty-nine members attended, many being accompanied by their wives. Preceding and following the meeting, small groups were shown the many interesting features of this institution. After luncheon a brief business session was held which was conducted by the President, Dr. Ralph M. Chambers.

The program contained many interesting features. The first series of cases was presented by Dr. S. O. Miller. This consisted of (1) Absence of Sternum, Congenital; (2) Demonstration of the Displacement of Migraine with Epilepsy; (3) Dislocation of Both Hips, Congenital. Dr. L. H. Wright's first case was an unusual presentation of argyria of 26 years' standing. The pigmentation was uniformly distributed and followed the admission of silver nitrate $\frac{3}{4}$ gr., daily, over a period of 5 months preceding her admission for epilepsy.

The second case presented the classical symptoms of myotonia in epilepsy. The Assistant Superintendent, Dr. W. F. Wood, concluded the program with two cases of rare interest. The first was one of chronic myelitis of 18 years' standing. The second of this group was one of the Charcot-Marie, tooth type, of muscular atrophy. Discussion of the latter by Drs. R. H. Greene and H. M. Watkins.

At this time, it was proposed that the August meeting be held at one of the beaches. Date and place will be announced later by the committee.

NEIL A. DAYTON, M.D., *Secretary*,
Wrentham State School.

LETTER FROM DR. P. PODYAPOLSKY.

American physicians who provided food last winter for members of their profession living in Russia, have been paid tribute by the recipients of the aid, through a letter of thanks from Dr. P. Podyapolsky, substitute professor at the University of Saratov. Dr. Podyapolsky in the letter received at the headquarters of the American Relief Administration, 42 Broadway, New York City, expresses his indebtedness and that of the needy medical men of Russia, for the gift of food packages sent them by their American colleagues.

The letter paints a vivid picture of the despondency into which some of the educated classes in Russia had fallen before the arrival of the food packages from the United States, and the gift corn purchased under the \$20,000,000 Congressional appropriation for Russian relief, as follows in abstract:

"Your hand stretching across the ocean, with a friendly, holiday surprise, staves off our destiny—our turn in the general disaster of the 'Titanic'—Russia! Oh, this box contains things we have not seen for a long time. You are creating for our children and ourselves the first bright holiday, and my wife who has been chained to her bed and whose sickness consists solely of having lost in the past four and one-half years about 90 pounds and the last bit of courage, will get up again! We are deeply moved by the pure, touching gladness which has illuminated the dark, languishing days of waiting for our fate. . . . And we do not feel now that we are left all alone, and it seems to us that everything around us is becoming brighter.

"My colleague, Dr. Matvieev, could not endure any longer and took strychnine a few days ago. . . . Nearly two years ago, our daughter, 26 years of age, a doctor of medicine, ended her young life with ten grams of sublimite—she was tired out, but proud and unshaken.

"Thanks to you, we are now experiencing a similar moment."

—*American Relief Administration.*

RHODE ISLAND MEDICAL SOCIETY.

THE annual meeting of the Rhode Island Medical Society, June 1, 1922, at the Medical Library, Providence, R. I., was called to order by President G. S. Mathews.

The minutes of the meeting in March of the House of Delegates and Council were read by Secretary J. W. Leech. No prize was awarded under the Fiske Fund on the subject of "Radium Therapy." The subject chosen for 1923 is "Has Surgery Lessened the Incidence of Cancer?" A prize of \$200 is offered for the best essay submitted.

The officers elected at the annual meeting for 1922-23 are as follows: President, F. E. Peckham, Providence; first vice-president, A. T. Jones, Providence; second vice-president, W. F. Barry, Woonsocket; secretary, J. W. Leech, Providence; treasurer, W. A. Risk, Providence.

Program.—(1) "Rickets and Tetany in Children," W. P. Buffum, Jr., Providence; (2) "Bodily Mechanics in Relation to Chronic Disease," Lloyd T. Brown, Boston; (3) "Hay Fever," Harry S. Bernton, Washington, D. C.; (4) "Some Aspects of the Treatment of Diabetes," Alexander M. Burgess, Providence.

The annual address of President Mathews dealt with the need of closer union of the district societies and the state society, with the nursing problem, etc.

The banquet was held at the Turk's Head Club, Dr. J. E. Mowry of Providence being the anniversary chairman. The speakers were Alonzo R. Williams, Esq., and the Rev. H. H. Hayes.

Obituary.

RESOLUTIONS ON THE DEATH OF EDWARD HALL NICHOLS.

SURGEON-IN-CHIEF TO BOSTON CITY HOSPITAL.

ON JUNE 12, 1922, EDWARD HALL NICHOLS passed from the staff of the Boston City Hospital, with which he had been constantly identified since his graduation from the Harvard Medical School in 1890. After completing his term of service as a surgical house-officer, he became successively executive assistant and assistant superintendent at the hospital, bringing to both duties the clear thought and decisive action which characterized his entire career. Upon leaving the executive office of the hospital, Nichols did not go immediately into prac-

tice, but became director of the Croft Cancer Commission, a position which he held for five years. He then conducted the Department of Surgical Pathology at the Harvard Medical School as instructor, demonstrator, and later as assistant professor, bringing to his surgical technique the fundamental knowledge gained in the laboratory. At this time his work upon bone diseases, especially osteomyelitis, tuberculosis of the bones and joints, and arthritis deformans, was noteworthy. From 1916 to 1918 he was clinical professor of surgery at the Harvard Medical School. In 1918 he was appointed professor of clinical surgery. Throughout his entire connection with the medical school he gave instruction in surgical pathology.

Dr. Nichols was commissioned an honorary lieutenant colonel in the British army during the World War and took over the Harvard unit. Later, as lieutenant colonel in the American army, he was the surgeon in charge of Base Hospital No. 7, and was cited by General Pershing "for exceptionally meritorious and conspicuous service at Base Hospital No. 7, Jougles-Tours, France."

At the meeting of the general staff, the chairman said, "The hospital has met with an irreparable loss," and these few words spoke volumes, for Nichols, through all his years, had given to the hospital his best. Of keen judgment and decisive action, he met the problems of surgery with a thorough knowledge of operative indications, and a thoughtful consideration of the patient's welfare. In executive matters he tried to analyze the underlying reasons and the motives which prompted the action. Intolerant of sham or pretense, strong in his likes and dislikes, his striking personality impressed all who knew him. He sought the truth and if wrong himself he was glad to accept the correction provided it was sound. Nichols never faintly praised; a thing was right or wrong, and he valued it accordingly.

Dr. Nichols was a rare man: an unusual and outstanding figure; a thoroughly trained surgeon capable of performing difficult operations; a clear and decisive teacher. His place in the hospital will be difficult if not impossible to fill; his loss will leave in our hearts a never-ending sorrow.

Correspondence.

"SOME FEATURES OF MEDICAL EDUCATION."

June 27, 1922.

Mr. Editor:

Your editorial with the title given above is admirable, and as an analytical showing of present conditions there is nothing to add to it. But there is one thing upon which I would place special emphasis now.

It is that very many patients are at an extreme loss to know, when they are ill, for whom to send. I confess that as an old general practitioner and with many of my former house physicians at the top, I do not know which one still does general practice. They are all, apparently, consultants, or specialists, and yet I, like all men and women, at any time may be ill. Personally, so long as I can, I will take care of myself, but that day and time is rapidly fleeting. Who, later, will be sent for as my doctor, I do not know, and, alas, I cannot advise, in view of what I have stated.

BEVERLEY ROBINSON.

129 East 35th Street, New York City.

THE COMMITTEE ON PUBLIC HEALTH.

Mr. Editor:

In your report of the proceedings of the Council at the meeting of June 13 you imply that the request of the Committee on Public Health for an appropriation was rejected by the Committee on Membership and Finance because the report of the former committee did not technically come before the latter in season for consideration, for "although it had appeared in the JOURNAL, the Committee on Finance did not regard that as a communication directly to it."

As chairman of the Committee on Finance, I tried to make it clear that this was not the reason, but that the vote of the Council in February had included the proviso that the Committee on Health must present to us, in the words of the vote, a "definite detailed plan" for the expenditure of the appropriation asked for.

No such "definite detailed plan" was presented to us, either early (as the vote directed) or late (if five days before the June meeting be late). And the only action that would enable us to come before the Council prepared to say that we had followed its instructions was, we thought—and still think—the action we did take.

We thoroughly discussed the communication when it reached us, as it did, from the hands of the chairman of the Committee on Public Health, and we were uninfluenced by the fact that a publication in the JOURNAL had preceded any direct communication with us.

"Detailed and definite" meant much to us: "early and indirect communication" meant little.

Very sincerely,

SAMUEL B. WOODWARD.

The vote of the Council is as follows:

"Voted, That the entire matter be referred to the Committee on Membership and Finance for a report at the next meeting of the Council, with the understanding that the Committee on Public Health will present to said Committee on Membership and Finance, at an early date, a definite, detailed plan for the expenditure of the appropriation asked for."
—Editor.

NEW YORK AND NEW ENGLAND ASSOCIATION RAILWAY SURGEONS.—The thirty-second annual session of the New York and New England Association Railway Surgeons will be held at the Hotel McAlpin, Broadway and 34th Street, New York City, on Saturday, October 28, 1922, under the presidency of Dr. Donald Guthrie of Sayre, Pa. A very attractive and interesting program is being arranged for this session.

DIGITALIS IN CARDIAC DISEASE.*

By HENRY A. CHRISTIAN, M.D., BOSTON.

IN seeking a topic on which to address you it seemed to me desirable to select one that concerned the majority of you and which might bring to you some suggestions that would be helpful in your usual routine of work. With this in mind, I suggested two topics to your committee, and they selected the one on digitalis therapy. I believe they made a good choice, for in my experience there are many misconceptions in regard to digitalis among practitioners, judged from their use of the drug on patients that subsequently have come under my care.

Certain more or less categorical statements may be made with advantage about digitalis, and some of these I will use to preface my remarks.

The dangers or toxic effects of digitalis are more serious as met with in medical books than in medical practice.

Some one of these toxic effects or so-called digitalis dangers really should be sought rather than avoided in digitalis therapy.

The real dangers in digitalis therapy are three:

- (a) Using a poor digitalis preparation.
- (b) Consciously or unconsciously prescribing too little of a potent digitalis preparation.
- (c) Not knowing when digitalis should be started and stopped.

Digitalis usually is given in too small, *i.e.*, insufficient, dosage. I have yet to see the patient in whom too much digitalis had been given prior to my seeing the patient. I have given too much, *i.e.*, a harmful dose of digitalis, myself, to my knowledge just once, knowingly then taking a chance in a desperate case. The large majority of cardiac patients seen by me have had too little digitalis; a small percentage have had enough digitalis; none have had too much; some have had too little from the point of view of dosage when actually they should have had none.

Digitalis poisoning, of course, is possible, but it is one of the rarities of medicine.

Digitalis is good for the symptoms and physical signs the patient has, provided those symptoms and signs are the result of cardiac insufficiency, *i.e.*, decompensation.

The indications for starting digitalis therapy are the presence of symptoms and physical signs which are the result of cardiac insufficiency, *i.e.*, decompensation.

The symptoms and physical signs of cardiac insufficiency are breathlessness, cough, cyanosis, edema, pain, weakness, nausea, vomiting, enlargement of the liver, decreased urine output, rapid pulse.

*Read May 10, 1922, at meeting of Iowa Medical Society, held at Des Moines, Iowa.

The indications for stopping digitalis are improvement in these symptoms and signs or the occurrence of some of the toxic effects of digitalis.

The toxic effects of digitalis are nausea, vomiting, certain arrhythmias, as bigeminal pulse and heart block, rarely diarrhea.

There are a number of misconceptions about digitalis therapy now in vogue, some very generally. Some of these are:

(a) that a regular pulse indicates that a poor digitalis effect will be obtained;

(b) that striking digitalis effects are confined to patients with auricular fibrillation;

(c) that a slow pulse indicates that a poor digitalis effect will be obtained;

(d) that a fast pulse is an indication for the use of digitalis;

(e) that a murmur is an indication for the use of digitalis;

(f) that cardiac enlargement is an indication for digitalis;

(g) that aortic insufficiency is a contraindication for digitalis;

(h) that myocardial degeneration is a contraindication for digitalis;

(i) that high blood pressure is a contraindication for digitalis;

(j) that arteriosclerosis is a contraindication for digitalis;

(k) that angina pectoris is a contraindication for digitalis;

(l) that nausea and vomiting are due to some undesirable constituents in the digitalis preparation that may be removed by pharmaceutical art.

Other misconceptions might be enumerated, but sufficient have been given to occupy us at present.

Now let us elaborate somewhat on those of the above statements that do not seem clear or for which further evidence appears to be desirable. As to the toxic effects and dangers of digitalis little need be added to what I have already said. The striking fact is that serious toxic effects and real harm from digitalis therapy are almost never seen. Very often symptoms regarded as the result of digitalis are really due to failure to give enough digitalis to control cardiac symptoms. So often digitalis is stopped or some other cardiac drug is used because of nausea, when it is more digitalis, not less, that is needed to abate the nausea.

It needs to be recognized that very often the digitalis which the patient purchases has but slight potency. A serious error is to regard a drop as a minim and to prescribe 15 drops of tincture of digitalis, thinking to give 15 minims; the patient taking 15 drops often gets but five minims, rarely more than seven—both very small doses. This error accounts for

CHART 1.—Male, age 28, chronic cardiac valvular disease, mitral stenosis; rhythm regular. The first column of figures on the left hand side of the chart indicates the amount of urine output and the fluid intake for each 24 hours expressed in c.c. The second column of figures on the left of the chart indicates the apex and radial pulse rates per minute. D=3 doses of 0.2 gm. each of powdered digitalis leaves every 6 hours, a total of 0.6 gm. on this day. D=7 doses of 0.3 gm. each of powdered digitalis leaves every 6 hours, a total of 2.1 gm. on this day. Total D+D=2.7 gm. of powdered digitalis leaves. P=pulse rate counted at the wrist. F=fluid intake measured in c.c. U=urine measured in c.c. The effect of digitalis in this case was a slowed pulse (110-55) and on two days a marked diuresis, with urine increase from 400 to 2700 and 2500 c.c.

CHART 2.—Male, age 60, chronic myocarditis, rhythm regular. The first column of figures on the left hand side of the chart indicates the amount of urine output and the fluid intake for each 24 hours expressed in c.c. The second column of figures on the left of the chart indicates the apex and radial pulse rates per minute. The column of figures on the right indicates the weight of the patient in kilograms. D=3 doses of 0.2 gm. each of powdered digitalis leaves every 6 hours, a total of 1.6 gm. P=pulse rate counted at the wrist. F=fluid intake measured in c.c. U=urine measured in c.c. W=weight of the patient in kilograms. The effect of digitalis in this case was a moderately slowed pulse rate (85 to 60), a diuresis with urine increase from 625 to 975 and 2200 c.c., and a decrease in body weight of 7.8 kilos, or 17.2 pounds.

CHART III.—Female, age 43, chronic myocarditis, auricular fibrillation. The first column of figures on the left hand side of the chart indicates the amount of urine output and the fluid intake for each 24 hours expressed in c.c. The second column of figures on the left of the chart indicates the apex and radial pulse rates per minute. The column of figures on the right indicates the weight of the patient in kilograms. D=0.5 gm. of powdered digitalis leaves given at 3:35 p.m. P=9 doses of 0.2 gm. each of powdered digitalis leaves, given four times a day, a total of 1.8 gm. Total D+D=2.3 gm. of powdered digitalis leaves. A=heart rate counted with a stethoscope over the apex region. P=pulse rate counted at the wrist. F=fluid intake measured in c.c. U=urine measured in c.c. W=weight of the patient in kilograms. The effect of digitalis in this case was a diuresis with urine output of 2250 c.c. and a decrease in body weight of 7 kilos, or 15.4 pounds.

much unconscious prescribing of too small a dose. The rest comes from the digitalis being of low potency. I would urge on you the abandoning entirely of directing your patients to take any number of drops of digitalis tincture; most desirable doses contain too many drops to ask your patient to use such a crude method of measurement.

All too often digitalis is given on the part of the physician when the indications for its use are not evident. There should be definite evidences of cardiac insufficiency before digitalis is given. Increased heart rate alone is never the result of cardiac insufficiency and never the indication for digitalis therapy. This may seem a strong statement, but following it will, I am sure, improve your digitalis therapy and save you from giving it when it will do no good and may do harm. Paroxysmal tachycardia does not respond to digitalis and digitalis does not affect simple tachycardia. In infectious diseases a rapid regular pulse, in my opinion, is not an indication for

CHART IV.—Female, age 28, chronic cardiac valvular disease, mitral stenosis and regurgitation, aortic regurgitation, auricular fibrillation. The first column of figures on the left hand side of the chart indicates the amount of urine output and fluid intake for each 24 hours expressed in c.c. The second column of figures on the left of the chart indicates the apex and radial pulse rates per minute. D=1 c.c. tincture of digitalis given intravenously at 10:12 a. m. P=2 doses of 0.5 gm. of powdered digitalis leaves at 1:52 and 8 p. m., a total of 1 gm. D=2 doses of 0.1 gm. of powdered digitalis leaves given at 6 and 10 p. m., a total of 0.2 gm. Total D+D+D=1 c.c. of tincture intravenously and 1.2 gm. of powdered leaves by mouth. A=heart rate counted with a stethoscope over the apex region. P=pulse rate counted at wrist. F=fluid intake measured in c.c. U=urine measured in c.c. The effect of digitalis in this case was a slowed apex rate (190 to 70), with disappearance of pulse deficit.

digitalis, and its use will do your patient no good. I see no advantage in the routine use of digitalis in pneumonia, a quite usual procedure. In the pneumonia doing badly with a rapid, weak pulse, I have never seen digitalis help and I have stopped using it in such cases. If auricular fibrillation develops or cardiac decompensation is present, digitalis is very useful. It then behooves practitioners to recognize clearly what are the symptoms and signs of cardiac decompensation, and these I have already enumerated. Here I should add that no murmur of whatsoever sort, nor enlargement of the heart, in itself is an indication for digitalis therapy. If symptoms and signs of cardiac insufficiency are present, give digitalis until they improve, or until some of the toxic effects of digitalis appear. The remarkable thing is that but extremely few cardiac cases fail to show some improvement

CHART V.—Male, age 57, chronic myocarditis, auricular fibrillation. The first column of figures on the left-hand side of the chart indicates the amount of urine output and fluid intake for each 24 hours expressed in c.c. The second column of figures on the left of the chart indicates the apex and pulse rates per minute. The arrows of A^2 indicate days on which the patient received three doses of 0.1 gm. each of powdered digitalis leaves. A heart rate counted with a sphygmograph over the apex region. P pulse rate counted at the wrist. F fluid intake measured in c.c. Urine measured in c.c. The effect of digitalis in this case was a marked slowing of the heart rate from 140 to 74 and a diuresis with urine increase from 550 to 2525 and 5550 c.c. per 24 hours.

in some of the evidences of cardiac decompensation when adequate dosage of digitalis is used. In 97 consecutive adult cases of my own 81 showed definite symptoms or signs of cardiac decompensation; 90 per cent. of these showed definite improvement in cardiac condition following digitalis therapy. The nine failures resulted from close approach of death in six, aortic aneurysm in one, chronic nephritis that prevented diuresis in one, and there was no apparent reason in one.

That a regular pulse indicates that a poor digitalis effect will be obtained is not borne out by the chart of the following case. (Chart I.)

CHART VI.—Male, age 35, chronic myocarditis, regular rhythm. The first column of figures on the left-hand side of the chart indicates the amount of urine output and fluid intake for each 24 hours expressed in c.c. The second column of figures on the left of the chart indicates the apex and pulse rates per minute. Arrows over A^1 indicates intramuscular dose of 1 c.c. of digipuratum. Arrows over A^2 indicate days on which the patient received three doses of 0.1 gm. each of powdered digitalis leaves. P pulse rate counted at the wrist. F fluid intake measured in c.c. U urine measured in c.c. The effect of digitalis in this case was a marked slowing of the pulse from 130 to 72.

This patient was a male of 28 years of age, with mitral stenosis and regular rhythm. Digitalis produced a slowing of the pulse from 110 to 55, and on two days there was a marked diuresis, with urine increasing from 400 to 2700 and 2500 c.c. per 24 hours. Such good digitalis effects were obtained in 72.5 per cent. of a series of patients with a regular rhythm studied by me.

That striking digitalis effects are confined to patients with auricular fibrillation is not borne out by my experience. For in 97 consecutive adult cases, of which 10 had regular rates and 57 fibrillated, definite digitalis effects were obtained irrespective of regular rhythm or fibrillation, the percentage being 72.5 per cent. for

CHART VII.—Male, age 45, chronic myocarditis, hypertension, rhythm regular. The first column of figures, on the left-hand side of the chart, indicates the amount of urine output and the fluid intake for each 24 hours expressed in c.c. The second column of figures on the left of the chart indicates the apex and radial pulse rates per minute. The column of figures on the right indicates the weight of the patient in kilograms. Dose single dose of 2.3 gm. of powdered digitalis leaves given at 10:20 a. m. P—pulse rate counted at the wrist. F—fluid intake measured in c.c. U—urine measured in c.c. W—weight of the patient in kilograms. The effect of digitalis in this case was to produce a very marked diuresis with increase of urine from 1000 to 6425, 5050, 2625 and 2600 c.c., and a decrease in body weight of 21.4 kilos, or 47 pounds.

regular rhythm and 75.4 per cent. for auricular fibrillation.

As to a slow pulse indicating a poor digitalis effect, the charts of the following cases show that this does not hold true. The first patient was a male, age 60, with chronic myocarditis and regular rhythm. In this patient the effect of digitalis (Chart II) was a very moderate slowing of the pulse rate from 85 to 60, an increase in urine output from 625 to 975 and 2300 c.c. per 24 hours, and a decrease in body weight of 7.8 kilos, or 17.2 pounds. The second patient was a female, age 45, with chronic myocarditis and auricular fibrillation. The effect of the digitalis in this case (Chart III) was a diuresis, increasing the urine to 2250 c.c. in 24 hours, and a decrease in body weight of 7 kilos, or 15.4 pounds.

As to aortic insufficiency being a contraindication for digitalis, it is generally held now that digitalis does not at all increase the probability of the heart stopping in diastole on the theory that digitalis prolongs diastole in its slowing effect on the heart and so increases the regurgitation of blood back from the aorta, leading to overdistention of the left ventricle. Perhaps excellent digitalis effects are not obtained as regularly with aortic insufficiency as with other valve lesions, but often they are extremely satisfactory, as shown by the chart of the following case. This patient was a female, age 28, with aortic regurgitation and mitral stenosis and regurgitation. She had auricular fibrillation. The effect of digitalis (Chart IV) was to slow the apex rate from 190 to 70 and cause a disappearance of the pulse deficit.

The statement that myocardial degeneration is a contraindication for digitalis is not in harmony with the striking effects obtained in auricular fibrillation, which is an indication of myocardial disease. Nor is it in accord with the splendid results of digitalis obtained in chronic myocarditis, as already illustrated by Charts III and IV. Chart V, of a middle-aged man with chronic myocarditis and auricular fibrillation, shows particularly well a digitalis effect with slowing of the apex rate from 140 to 74 and a diuresis from 700 to 2550 and 5100 c.c. per 24 hours. Even with pulsus alternans, one of the best indications we have of severe myocardial disease, splendid results may follow digitalis, as shown in the following case. Here, in a man of middle age with chronic myocarditis, the electrocardiograms showed a regular cardiac rhythm, but tracings from the brachial artery indicated a marked degree of pulsus alternans. Digitalis under these conditions, however, produced (Chart VI) a marked slowing of the pulse from an average of 125 to 72. In just the same way, hypertension, arteriosclerosis and angina per-

toris are not contraindications for digitalis. With all of these excellent digitalis effects are obtained. The following cases may serve to illustrate this. In the first patient of this group there was a chronic myocarditis with hypertension and a regular cardiac rhythm, in a male, age 45. Digitalis here produced (Chart VII) a very marked diuresis, increasing the urine from 1000 c.c. to 6425, 5050, 2625 and 2600 c.c. per 24 hours, and decreased the body weight by 21.4 kilos, or 47 pounds. In a second case there was hypertension and chronic myocarditis in a woman of 43 who had

a regular cardiac rhythm. Here the effect of digitalis was (Chart VIII) a slight, prolonged diuresis and a decrease in body weight of 15 kilos, or 33 pounds. In a man of 59, with chronic myocarditis, auricular fibrillation, marked arteriosclerosis and a former right-sided hemiplegia, digitalis produced (Chart IX) a delayed decrease in the apex rate from diuresis and a decrease in body weight of 19 kilos, or 41.8 pounds.

Finally a word as to the misconception that nausea and vomiting are due to some undesirable constituent of digitalis that may be removed by pharmaceutical art. Hatcher's experimental work has shown clearly that nausea and vomiting are central toxic effects of digitalis on the vomiting centre and not a local action on the gastric mucosa. My own experience has been that digitalis in its simplest form, namely, as powdered leaves, does not produce nausea and vomiting until other definite digitalis effects are manifest, and that it

CHART VIII.—Female, age 43, chronic myocarditis, hypertension, rhythm regular. The first column of figures on the left-hand side of the chart indicates the amount of urine output, and the fluid intake for each 24 hours expressed in c.c. The second column of figures on the left of the chart indicates the apex and fluid pulse rates per minute. The column of figures on the right indicates the weight of the patient in kilograms. D—a single dose of 1.2 gm. of powdered digitalis leaves given at 9:30 p.m. D'=0.5 dose of 0.6 gm. each of powdered digitalis leaves every 6 hours, started at 5:50 a.m., a total of 1 gm. fluid D=0.5 gm. of powdered digitalis leaves. P—pulse rate counted at the wrist. F—fluid intake measured in c.c. U—urine output in c.c. W—weight of the patient in kilograms. The effect of D in this case was a slight prolonged diuresis, and a decrease in body weight of 15 kilos, or 33 pounds.

CHART IX.—Male, age 59, chronic myocarditis, auricular fibrillation, arteriosclerosis, old right hemiplegia. The first column of figures on the left-hand side of the chart indicates the amount of urine output and the fluid intake for each 24 hours expressed in c.c. The second column of figures on the left of the chart indicates the apex and radial pulse rates per minute. The column of figures on the right indicates the weight of the patient in kilograms. D=0.2 gm. of powdered digitalis leaves. D'=15 doses of 0.1 gm. each of powdered digitalis leaves every 6 hours, a total of 1.5 gm. Total D D'=2.5 gm. of powdered digitalis leaves. A heart rate counted with a stethoscope over the apex region. P—pulse rate counted at the wrist. F—fluid intake measured in c.c. U—urine measured in c.c. W—weight of the patient in kilograms. The effect of digitalis in this case was a delayed decrease in apex rate (110 to 78), with a moderate decrease in pulse deficit, a delayed but prolonged moderate diuresis, and a decrease in body weight of 19 kilos, or 41.8 pounds.

may be used advantageously in almost every cardiac patient, even when nauseated and vomiting. I have often tried preparations supposed to have been freed of their objectionable gastric action. The result uniformly is that either they produce nausea and vomiting just as promptly as the simple powdered digitalis, or if they do not, it is because they are not potent preparations, *i.e.*, they do not give satisfactory digitalis effects. My own experience is that digitalis lutea, claimed to have less toxic effects than digitalis purpurea, produces the same nausea when the two are used in corresponding dosage. I doubt whether it is very likely that a digitalis preparation will ever be produced which will give satisfactorily digitalis effects and not cause nausea. I even question whether such a preparation is really desirable. Nausea is, after all, a very useful, easily recognizable effect of sufficient digitalis, and so serves a very useful purpose in digitalis therapy. If one is carefully watching his patients, in many instances full therapeutic effects of digitalis may be obtained without causing nausea, and if nausea does result it need not be severe. Marked nausea and vomiting occur in reverse ratio to the care that is being given to the observation of one's patients. Anyhow, I firmly believe that so far no pharmaceutical art has succeeded in removing the nausea-producing portion of digitalis and leaving behind its needed therapeutic portions. After a fair trial of the various available digitalis preparations, I feel convinced that none are superior to digitalis in its simplest form: the leaves powdered and mixed with a sticky vehicle so as to make a pill.

Digitalis may be given in a single massive dose, or in a modified massive dose method, or in regularly repeated small doses. Any of these methods is effective. The chief difference lies in the length of time needed to produce a result. For the average cardiac case there is no real preference. In a few very severe cases the modified massive dose method is better. Occasionally the single massive dose may be life-saving. When all is done and said, digitalis therapy is very simple. Just give enough of a potent leaf, prepared in any way, by any accepted method of dosage, and the result is most satisfactory in almost every case. So far I have never seen a patient to whom digitalis could not be given when it was indicated by symptoms and physical signs without doing the patient harm, and almost always with excellent results. I know of no cardiac case in which it is necessary to substitute any other drug for digitalis, and I consider powdered leaves of digitalis in pill form a thoroughly satisfactory preparation. In seven years' use at the Peter Bent Brigham Hospital I have seen digitalis leaves of different

strengths, but so far we have never purchased a leaf that was unsatisfactory in its results, and except for periods of testing some particular preparation, we have consistently adhered to using powdered leaves in pill form because the results were thoroughly satisfactory. We have found that using a new sample of leaves on a group of patients was an eminently satisfactory way of finding out the potency of the leaf and the most effective dosage. Standardizing on animals is helpful but by no means essential. For much of the time we have not standardized our leaves on animals and still our results are satisfactory. I am saying this not to decry animal standardization, but merely to show that it is not essential to good digitalis therapy in the hands of one with as much as several cardiac cases constantly on hand for treatment.

QUACKERY, MIRACLE HEALING AND MEDICAL CULTS.*

BY ROBERT W. LOVETT, M.D., BOSTON.

If one goes backward in the history of civilization, one finds wherever and whenever one looks into it, three persistent parasites clinging to each successive stage of civilization. These are drunkenness, prostitution, and quackery. The State legislates against them; the Church fulminates against them; the better part of the community from time to time rises and decides to exterminate them; but in the Vedas of India, the classics of Greece and Rome, the early records of Egypt and Arabia, and the writings of the Middle Ages, you will find that parasite with which we are for the moment concerned — quackery — described, deplored, and condemned in terms almost of today.

To maintain such vigor, such persistence and such superiority over all the efforts of Church, State and Society to overcome it, quackery must have deep roots in human nature, and it is of interest to inquire what these roots are.

Causes of Quackery.—The first of these lies in human gullibility. It has never been better expressed than by Butler in the following lines from Hudibras:

"The world is generally averse
To all the truths it sees and hears;
But swallows nonsense, and a lie,
With greediness and glutting."

Our own Barnum phrased it more graphically, if less elegantly, in his statement that "the public loves to be humbugged."

Our special community, however, is well-educated and advanced and should presumably not be the prey of every chance faker. It should

*Read before the Harvard Medical Society, April 11, 1922.

not be; but what shall be said of the gullibility of a community, which not so long ago financed so very handsomely the enterprise of Ponzi, and similar preceding enterprises like Mrs. Howe's bank? The local soil for such enterprises is evidently a fertile one and the community not so enlightened as one might wish.

Further reasons for the persistence of quackery are found in the existence of one of the classes in the community described by Abraham Lincoln in his classical dictum: "You can fool all the people part of the time, and part of the people all the time, but you can't fool all the people all the time." The part of the people that can be fooled all the time includes several groups, each of which is fertile soil for the quack: (1) the very ignorant; (2) a peculiar class which seeks the mystical, the occult, and the irregular; (3) an unreasonable class, which espouses an unpopular cause, simply because it is unpopular, without any investigation of its merits, and which finds in the occult mysticism of India a satisfaction which does not come from the contemplation of facts as they are. One might describe them as a submerged class,—submerged in the matter of reason and common sense.

The proportion of the gullible class in any community varies, but the estimate of a celebrated quack may be of interest. "He was visited by a former playfellow from his native village, who asked how he had got on so well, adding with the frankness of early friendship, 'Thee knowst thee never had no more brains than a pumpkin.' The quack took him to the window and bade him count the passersby. When a hundred had passed the quack asked his visitor: 'How many wise men do you suppose were amongst this hundred?' 'Mayhap one,' was the reply. 'Well,' returned the quack, 'all the rest are mine.'"

A cause which must not be forgotten lies in the earliest development of medicine. The early conception of disease was that it was due to an evil spirit which had entered the body of the sick man and to drive out this evil spirit were used incantations, exorcism, magic, charms, amulets, etc. Traces of this affiliation between medicine and magic persist today, perhaps not altogether unnaturally when one looks back on the thousands of years during which they were affiliated, and the comparatively few centuries in which they have been separated.

On February 6, 1921, in the Municipal Court, of Boston, there was sentenced to a year in prison a Professor L. P., styling himself the 7th son of the 7th son, and holding himself out as a clairvoyant and palmist. He had a birth mark on his breast, which he exhibited, and said was his instrument of cure, which never failed if his patients followed his instructions closely. He promised to cure a young man, crippled with

rheumatism; another son, who was also crippled, and the mother, who suffered from the same affection.²

The family had to sign a contract that they would not eat anything which contained vinegar, and a medicine was left which consisted of cigarette water. The first patient was to rub this on his knees once a day for 4 days, and on the 4th day would be cured. It was added, however, that perhaps for a few days more there would be a slight stiffness in his legs—the result of having been confined to a wheel-chair for many years. The brother was to rub the backs of his ears with the medicine for 3 or 4 days; and the mother was to rub the same medicine on the soles of her feet, also for 4 days. A cash fee of \$22.81 was received, but the professor failed to make a favorable impression on the family, and they did not use the medicine, but instead had him arrested.

The point of the story is that this incident of the presence of the witch doctor in our midst, occurred in Boston in the current year, and the evidence brought out in court showed that this man had been arrested for the same sort of thing before in Worcester and in Maine, and was wanted in Salem for a similar offence.

In the history of the past there is no more amusing group of rogues than the famous quacks of the ages. Facile, specious, without conscience, and with unlimited daring, they come down through the years, not depressed by adversity and always ready to trade on human gullibility.

Comparison of Different Ages of Quackery.—A question whether or not quackery is as generally prevalent today as it was in the past is of interest. Unfortunately there are no figures at hand from which to make accurate deductions; but one thing is certain—quackery today is decidedly less picturesque. A curious point of comparison is found in two Temples of Health: One flourishing in London, just before the French Revolution, and the other presided over in Kansas City by a man named Carson about 1910.

The original Temple of Health,³ in England, was established by one of the most impudent quacks who ever lived, James Graham by name, who at one time honored Philadelphia by his presence, practising as an itinerant oculist and aurist, but who returned to London and established himself there. His Temple of Health was situated in Pall Mall, with a richly ornamented facade. Two guards, in flowing robes with cuirasses of metal over them, stood at the entrance and collected from each visitor a fee of 6 guineas. When one entered the building, harmonious strains of music from hidden musicians attracted the ear, while subtle perfumes entranced the sense of smell. The visitor progressed to a magnificent hall, where garlands,

mirrors, crystal, gilt and silver, were scattered about with profusion to dazzle the eye.

When the audience was seated Graham entered in gorgeous doctor's robes, and delivered a lecture, at the close of which each auditor received an electric shock through an apparatus concealed in the cushion of his seat. When this penetrating intimation that the exercise was ended was received, the audience naturally rose spontaneously and departed without delay.

The modern Temple of Health in Kansas City seems to have been a more modest establishment and was described in the *Journal of the American Medical Association*.⁴ The proprietor, Carson, must have heard of the other Temple of Health, because he also provided entertainment; but the entertainment was of a different character, and the one which made the most trouble was an address by the Congregational minister of the town, who was subsequently somewhat criticized for lending his aid to this enterprise. Carson treated his patients by means of "vital force," rubbing them with vaseline mixed with red pepper—the latter producing the tingling due to the transmission of the "vital force." "Later he improved on this 'treatment' and had his assistants give out slips of tissue paper which he had 'magnetized.' These slips the patients were instructed to pin on their nightgowns between the shoulder-blades." Carson was exposed in the *Journal of the American Medical Association*, and in the *Independent*, and the State Board of Health of Missouri eventually prosecuted him for practising medicine without a license.

Types of Quackery.—Taking quackery and irregular practice from the time of Hippocrates (460 B.C.), the Vedas of India (600 B.C.), or the time of Galen, the stream flows down through the centuries in five main channels, and in analyzing these it will be interesting to see how little is new in modern cults. These channels are as follows:

1. Nostrums and Proprietary Medicines.
2. Miracle Healing.
3. Mental Healing.
4. Methods of Manipulation.
5. The Amateur Quack.

1. *Nostrums and Proprietary Medicine.*—These are sold in part with criminal intent and in part, probably, by stupid people, who believe in the efficacy of their concoctions. There is, however, no question of the intentions of the man who sold a morphine cure, containing morphia, or an inert cancer cure, or a disguised cocktail to innocent persons who were appreciative of the subsequent comfortable feeling, now described as "the kick," but ignorant whence it came. But thanks to *Collier's Weekly*, the *Ladies' Home Journal*, and the *Journal of the American Medical Association*, this busi-

ness has been thoroughly exposed; restrictive laws have been passed; extravagant claims can no longer be made on labels, and the United States mails are closed to such people on proper evidence. The account of the methods of these people and the crusade against them is to be found in a small book, called "The Great American Fraud," by Samuel Hopkins Adams, in a series of publications bound by the American Medical Association, and in weekly analyses of patent medicines and nostrums in the *Journal of the American Medical Association*. This wicked and cruel fake has been greatly damaged and the subject will not be dwelt on here to any extent.

The antiquity of this branch of quackery is doubted. So long as medicine consisted of charms, amulets, and incantations, not much could be done in the way of faking imitations; but when remedies became established, so did nostrums.

In this connection the most astonishing story in the whole history of quackery is the achievement of Joanna Stephens, a famous quack practising in London in the middle of the 18th century, whose remedies were supposed to have solvent action on stone and gravel in the bladder and kidney. "Not all the testimonies of Christian Science, Dowleism, the Emmanuel Society, and Lourdes, put together can show anything like such a list."⁵ Being a generous-minded woman, Mrs. Stephens had proposed to make her medicine public on consideration that the sum of 5000 pounds should be raised by subscription and lodged with a banker. The advantage of making public this wonderful remedy was taken up by the press, which urged that no humane or patriotic person could do otherwise than subscribe to the fund. In the list of subscribers are the names of bishops, dukes and duchesses, earls and baronets; but the subscription reached only 1336 pounds. Mrs. S., however, stood out for the original price, and application was then made to Parliament for that sum; and after a commission had seriously inquired into the cures, it was voted that the sum be granted. It is melancholy to read that in the list of those who signed the certificate, which was required by Parliament, were the names of such well-known medical men as Cheseldon, Caesar Hawkins, Samuel Sharp, and David Hartley. Mr. Hartley published some cases and experiments, which seemed to him to show sufficient evidence of the dissolving power of the remedy, in the urine of such persons as took Mrs. S.'s medicine. He concludes his statement in what seems to us today a rather illogical manner: "I, therefore, persuade myself that Mrs. S. will appear to you in a different light from common pretenders to nostrums and that you will not think the measures that have been taken for the pub-

lication of her medicine any encouragement to imposter."

When the grant of 5000 pounds, which in those days was a very considerable sum, had been made the secret was revealed. The remedy consisted of a powder, composed of egg shells and snails, calcined by heat, and a decoction made by boiling some herb along with soap, honey, swine cresses and a mixture of seeds of earrot, burdock and ash. With the knowledge of the remedy, interest in it ceased; but Mrs. Stephens had the money and Hartley died of the disease which the remedy was said to cure.⁵

2. *Miracle Healing*.—The subject of miracle healing is of established antiquity, but whether one view it from the point of view of the past or of today, it is too closely allied with religion to be discussed without the danger of giving offense.

It is to be divided into three main divisions: (a) miracles in response to prayer; (b) miracles claimed by Christian Science, such as the cure of cancer; and (c) miracles by the laying on of hands, with or without prayer. The first named is perhaps best seen in the miracle churches of Lourdes and St. Anne de Beaupré.⁷

In the work of Hickson, who was in Boston in 1919, and whose services were attended by great throngs of people, one finds the type of religious healer who works without financial reward. There is, however, from the medical point of view, danger in too wide a publicity of such statements as the following, credited to Hickson: "God can heal cancer as well as he can heal a headache; many so-called organic diseases have been healed through prayer. I say this out of experience."⁸

But along with the really religious healer, who uses the laying on of the hands, goes the unscrupulous quack, who also lays on the hands for pecuniary reward alone, without claim of special divine power.

A man of this sort visited Boston some years ago and gave public exhibitions in a large hall. I was one of the audience, and I have also attended the exhibitions of a man named Seblatter, given in a theatre. The former laid on hands, rubbed the patient's ears, told him he was better, or cured, and to get up and walk. Many of the people treated were obviously not confederates, and I saw instances of deafness apparently cured, lameness from rheumatism greatly improved, and cases where the sufferer said pain had wholly gone. The majority of patients, and all who were helped, were told that further treatment was necessary, for which they must report at a certain hotel the following day, and would be expected to make proper remuneration.

The daily press contains frequent communications upon miraculous cures, particularly of cancer.

According to one's mental make-up he either believes, or does not believe, in healing by miracle.

3. *Mental Healing*.—In this matter, also, too free discussion is likely to bring one into contact with religious belief and the subject can be dealt with only superficially. It may be divided into three main groups: Christian Science; The Emmanuel Movement; and Mesmerism.

A cure by mental healing implies an action of mind on body, not necessarily a direct miracle with the reversal of Nature's laws, but a healing by the natural mechanism of the body. This is best exemplified in Christian Science, which also figured in the last section; and those interested will find ample literature at their disposal.

The Emmanuel Movement was based on the assumption that medical men did not sufficiently use the spiritual and mental aspect of therapeutics in their treatment of the sick, and that this could be supplied from the outside, preferably by the Church. The enterprise has been free from any mercenary taint and has endeavored to work with the physicians. There is plenty of literature concerning it for those interested. One quotation may be given.—"Chronic ailments of every sort yield as if by magic to the benign influence of suggestion:—headache, toothache, neuralgia, rheumatism, insomnia, epilepsy, hysteria, neurasthenia, alcoholism, morphine, tobacco, stammering, sciatica, St. Vitus' dance, nervous dyspepsia, constipation, goitre, tumors, paralysis, etc. In this, and a hundred other ills, the law of suggestion understood by some friend, minister, or physician, can bring the blessing of health to thousands of pain-racked sufferers."⁹

In the light of this remarkable power, it is rather difficult to understand why one should give up after the first attempt, yet the following quotation shows us that such has at times been the case. "I will say frankly that I have not attempted the cure of locomotor ataxia, after my first case, which was not a cure, although I was able to cure him of his perverted moral troubles . . . I have not had universal success in treating the morphine habit."¹⁰

Healing by Hypnotic Suggestion and Mesmerism.—This measure, a legitimate and useful one in the hands of the qualified physician, suggests glorious, golden possibilities, in the hands of quacks, which have been largely and harmfully exploited. This cult is credited to Mesmer, for whom it is named. He summed it up as follows: "There is only one malady in all the world and I have the remedy for that at the end of my finger." Mesmer staged his private practice very alluringly and appeared

in a purple robe, embroidered with brilliant flowers, a color scheme which was characteristic of his daring in other matters. Holding the patient in his arms, while sweet or stimulating music was played, he gazed into her eyes and expressed his eagerness to cure. Hysteria, spasms, or hypnotic calm resulted, after which the patient was completely cured of all her ills. Naturally, only the rich were able to avail themselves of this wonderful opportunity, but Mesmer loved his fellow men like Abou Ben Adhem, and grieved that they should be shut out from the benefits of his wonderful powers; so he magnetized a tree on the Boulevard, and by standing under this pennurious invalids could receive the benefits of health without expense.

4. *Methods of Manipulation.* — Bone-setting, osteopathy, and chiropractic.

All other forms of irregular healing have at the present time largely given place to those by methods of manipulation. Of the three manipulative sisters, bone-setting, osteopathy, and chiropractic, bone-setting, as the oldest of the three, deserves first consideration.

Bone-setting. — Reference to manipulative treatment, akin to bone-setting, is found as early as the days of Homer, and it is probable that its origin is even earlier than this, although actual record of it seems to be lacking. "Among the other camp followers of medicine were the gymnasts or Iatroleiptes, who, besides exercises, practised inunction of the body. They were also, it would appear, bone-setters, and were naturally led to give first aid in all accidents and in many diseases, and to advise as to diet and regimen."¹¹

Howard Marsh¹² gives us the following clue to the origin of bone-setting: "Chirurgery, or hand-working, began in attempts to pull in displaced bones, to straighten distorted joints, and to restore movement to stiff limbs. In this dawn of the art nothing was known of anatomy or pathology; it was only seen that a limb was bent or stiff, and force was employed to overcome the defect, just as it might be used to straighten a crooked bar, or loosen a rusty lock."

In 1599 we find reference to bone-setting in Madrid,¹³ and a book entitled, "The Complete Bone-setter,"¹⁴ published in England in 1665, is suggestive that bone-setting was flourishing in that century. From that time on, the art has been much in vogue, especially in England. It has never existed as a science, but the art has in general been secretly handed down from father to son, and bone-setting families are known in America to this day, and a well-known bone-setter, Daniel Putnam, was established in Connecticut in 1670.

That a system of manipulation persists for something over 2,000 years is suggestive that

it probably possesses some therapeutic value, and although we might marvel at the pretensions and notoriety achieved by the celebrated bone-setter, Mrs. Mapp, in the middle of the 18th century, we will find that Mr. Barker, of Park Lane, London, does not today fall so far behind her.

Mrs. Mapp was the daughter of a famous bone-setter, and the sister of the celebrated Polly Peachum, who married the Duke of Bolton. She was popularly known as "crazy Sally," and was a strolling performer until Epsom offered her 100 guineas to continue there for a year, so great was her success. She married at Epsom, but unhappily, because Mr. Mapp was evidently temperamental and, after thrashing her several times, he went away with a large part of her earnings. She was much in the public press, and her cures were said to be too many to be enumerated. Her bandages were neat, and her skill in reducing dislocations and in setting fractures was said to be wonderful. If it was known that she was going to the theatre, that was sufficient to fill the house. Her own estimate of herself is shown by an interesting incident: When passing through Kent street, she was taken for one of the King's German mistresses, who was unpopular. A mob gathered and used threatening languages. Mrs. Mapp, thereupon, put her head out of the window and cried: "Damn your bloods, don't you know me? I am Mrs. Mapp, the bone-setter," and drove away amid the applause of the multitude.¹⁵

Mr. Percival Pott, the celebrated surgeon, who was her contemporary, spoke of her claims as "the most extravagant assertions of an ignorant, illiberal, drunken female savage."¹⁶

At the present time in London there is a bone-setter, Mr. Barker, nearly as well-known as Mrs. Mapp was, and about whose head has raged a storm of controversy. He is the legitimate successor of the great bone-setter Hutton, having served apprenticeship under Atkinson, who was Hutton's pupil. He claimed at his trial, in 1911, that he had at that time treated 30,000 cases, with 90 per cent. of success, most of whom had previously consulted, ineffectually, well-known practitioners. The trial alluded to above was the result of a suit for negligence against Mr. Barker, brought by a patient for manipulating a tuberculous knee twice, a proceeding which was followed by amputation. So far as one can judge from the newspaper reports, Barker made none too good a showing at the trial, but inasmuch as the jury awarded a verdict of only \$120, his offence was evidently regarded as not being a very serious one.

The *Times*¹⁷ has proclaimed him with his anesthetist, Axham, as "benefactors of the public," and during the war a petition was addressed to the Archbishop of Canterbury, praying him to confer the Lambeth degree of M.D.

upon Mr. Barker. The petition was not successful.¹⁸ In the petition it was stated that he was probably doing more to relieve suffering humanity than any living surgeon. The Prime's refusal to grant the petition was prefaced by the hope that "some means may be found of marking the country's appreciation of what I can but call Mr. Barker's eminent services to sufferers."¹⁹

His patients have included members of both houses of Parliament, and their families; the Episcopal Bench; the Cabinet; the Navy; the Army; members of both Universities; prominent sportsmen; barristers; soldiers; and frequently registered practitioners themselves. They come from the United Kingdom, India, Australia, New Zealand, Africa, Canada, and the United States.

The standing of Mr. Barker is curious, for on the one hand a proposal to knight him has been made, and on the other hand his anesthetist, Axham, has been disqualified from practice because he etherized for an irregular practitioner. The case has been argued in Parliament and the bitterest views, on both sides, have been expressed.

Mr. Barker has offered to explain his methods to a properly constituted committee of medical men, but Mr. Barker is irregular and, therefore, cannot be dealt with by the English profession. Yet Mr. Barker has not become regularized. Without casting aspersions upon his reasons for wishing to remain irregular, the following story, which appeared in the French papers²⁰ a few years ago, may be of interest. A quack, at a fair near Paris, was selling nostrums, drawing teeth and attracting an enormous crowd, who parted readily with their money. The offence against the French law was so flagrant that he was arrested and taken to a tent, where he was requested to show his diploma. To the surprise of his captors he produced a perfectly authentic degree of Doctor of Medicine from the University of Paris. The police, thereupon, began to apologize, but he cut them short and begged them to say nothing of what they had seen. "For," he said, "if the people know that I am a qualified doctor I shall have no more customers."

The *English Review* sums up the Barker situation as follows: "The Faculty cannot, and Barker shall not;" but Sir Arbuthnot Lane, in the course of a series of clinical lectures, put it more correctly when he said: "The bone-setter flourishes because the surgeon is deficient in a certain knowledge."

Fortunately we have a scientific analysis of bone-setting by Dr. Wharton Hood of England, M.R.C.S., published 50 years ago.²¹ Hood had an unusual opportunity to study bone-setting. It came about in this way: His father, Dr. Peter Hood, attended Mr. Hutton, the famous

bone-setter, through a long illness and refused to take a fee after Mr. Hutton's recovery. The latter, out of gratitude, offered to explain all the details of his practice and art. The senior Mr. Hood was unable to avail himself of the opportunity, and the invitation was then extended to his son, who attended Mr. Hutton's office hours and was taught by him. Later, during another illness of Mr. Hutton, Hood took charge of his charity patients, and upon Mr. Hutton's death he published an analysis of the method.

Mr. Hutton came of a family of bone-setters, but was an upholsterer during his earlier years. Referring to him, Howard Marsh,²² who was no friend of bone-setters, described him as "*facile princeps*" and "probably as good a bone-setter as ever lived." . . . "He treated anatomy with contempt; he neither knew nor wanted to know anything about it. He was a kind-hearted and perfectly honest man. He neither knew nor cared to know what the real condition was with which he was dealing, so that both he and his patient were playing a game of chance. He often said: 'I can cure you; what more do you want?'" Dr. Hood relates: "He had but a plain education, was entirely destitute of anatomical knowledge, and firmly believed the truth of his ordinary statement that the joint was out." Hood was at first afraid of using too much force, but after considerable experience with Hutton concluded that this was not to be feared. One must be careful, however, not to forget the skill and dexterity of Mr. Hutton in this relation. That accidents may and do occur in hands less skillful than Mr. Hutton's is well known, and was called attention to by Paget, who spoke of a fractured arm, and Proll reported in the *Lancet* two cases where suppuration and death had occurred after manipulation.

The manipulation consists in finding the spot that is painful to pressure, fixing it with the thumb, grasping the limb with short leverage on both sides of the joint with the thumb still kept in place, submitting the joint to flexion or extension or both, or putting it through other motions in the accomplishment of which resistance is encountered. The resistance is minimized by rotating the bone on its own long axis. Details of the manipulation are given in Wharton Hood's book.²³

The treatment of spinal lesions is most important to remember in considering the relation of bone-setting to osteopathy, remembering that it was published in 1871 and osteopathy "discovered" in 1874, and one has only to read the description of the manipulation for treating spinal lesions in Hood's book and the description of the treatment of the same condition in "*Osteopathic Mechanics*,"²⁴ published in 1915, to see that the methods are practically identical.

Before proceeding to the derivatives of bone-setting, osteopathy and chiropractic, it may be well to consider for a moment in what way bone-setting is of the value that it undoubtedly often proves to be.

The surgical world has been on the whole indifferent to the late effects of trauma on joints in producing slight degrees of stiffness or restricted motion. It is a good surgical axiom that a partially stiff joint is always a vulnerable one. The stiffness is due to adhesions, intra-articular, extra-articular, capsular shortening, adhesions of tendons or muscles, and to adaptive muscular shortening. Why they are as detrimental as they surely prove themselves to be is not always easy to explain, except that they restrict normal motion and consequently normal contacts of articular surfaces. If unilateral they cause a twist of the joint in its use, and in use the adhesions are constantly pulled on and irritated, and many a troublesome joint needs only to have its full arc of motion restored to become useful. That the spine is the part of the body on which two of these manipulative cults center their attention seems explained by the fact that between the occiput and sacrum there are 134 separate joints.

Osteopathy on analysis seems to be bone-setting, not much modified, but to which has been added a fantastic and unproved pathology to account for the claimed efficiency of its methods. An interesting quotation may be taken from one of the standard osteopathic text-books: "There is no doubt in my mind as to the similarity existing between the conditions which were recognized by so-called 'bone-setters' and those which have formed the basis for the successful advance of osteopathy. The difference lies principally in the educational qualifications."²⁵ After reading the osteopathic theory of disease one comes almost to admire old Mr. Hutton, who openly announced that he neither knew nor cared to know anything about anatomy.

Osteopathy is said to have originated with Dr. A. T. Still, who first announced its principles in 1874. When he was a boy he suffered from headache. One day he lay down under a tree with the back of his neck in a swing rope and fell asleep, and when he awoke the headache was gone. In 1874 he began devoting his whole time to the development of his science, and it is noted in osteopathic books that he received the same treatment that was accorded to Harvey in the 17th century when the latter discovered the details of the circulation of the blood.²⁶ In 1892 he established a school.

The theory of osteopathy as advocated by Still, who was a doctor of medicine and a veteran of the Civil War, is that the human body

is an exact mechanism properly balanced; that health consists in harmonious adjustments along mechanical, mental and dietetic lines; that slight disturbances of anatomic relations have manifold and far-reaching effects on bodily health and that treatment consists in the readjustment of these displaced parts. "These disturbed relations may occur in any of the structures of the body, so that we may have faulty adjustments of bones, ligaments, muscles, nerves, organs, or even of cells."²⁷ Obstruction in the spinal column from vertebral displacement may be occasioned at the intervertebral foramina through which emerge nerves and vessels.

The central thought of the science of osteopathy is the "lesion," which has been defined as "any structural perversion which produces or maintains functional disturbance. . . . Lesions are the result of injury, direct or indirect. . . . The term 'lesion' has been used in a restricted sense to mean any anatomical irregularity of a joint abnormal to the individual and the result of injury originating without the joint and intrinsic or extrinsic to the organism itself. . . . A subluxation is an immobilization of a joint in a position of normal motion, usually at the extremity of a given movement."²⁸ A more modern point of view than this would be to substitute the term "osteopathic lesion" for "subluxation." Just how these lesions produce the effects attributable to them clinically is not explained in the books consulted, and "Osteopathic Mechanics" passes at once to the details of adjustment.

With regard to this new pathology, in favor of which we are to discard all our present ideas, it must be remembered that mere assertion does not establish facts.

Voliva, the successor of Dowie in Zion, under the date of February 1, 1922,²⁹ asserts that the world is a flat plain surrounded by ice and that the sun is a small body about 40 miles in diameter, 3000 miles away. The sky is a dome of solid material from which the sun, moon and stars hang like chandeliers from a ceiling. Although a certain number will believe this assertion, the larger number will demand proof. And so, in valuing osteopathy, one has a right to ask for proofs that this new osteopathic pathology is correct.

It is therefore interesting to examine the tangible evidence as to this, which has so far been offered. Three varieties of proof are available:

1. In the dissecting room and at autopsy: The claim is made that dissections of bodies reveal anatomical lesions associated with disease of organs; these observations have been made at osteopathic colleges, but such changes have not been observed in the dissecting rooms of the medical schools of the world. The claim

that these "lesions" are found is, therefore, apparently not substantiated by sufficient evidence, which is eagerly awaited.³⁰

2. The x-ray: It is claimed that the x-ray has frequently shown an osteopathic lesion which disappeared after reduction. The experience of the medical profession is otherwise. It has only to be remembered how slight a distortion in the line of the shadow will produce the appearance of a displacement in an x-ray, and that the reading of an x-ray differs greatly. I can only state that in my personal experience in one or two instances I have been privileged to have taken in my own x-ray room, under fixed conditions, radiographs before and after the so-called "reduction" of a lesion by others. The closest analysis of the radiographs before and after failed to show the slightest change in the position.

3. Animal Experimentation: Bulletin V. of the A. T. Still Research Institute of Chicago, Illinois, published in 1917, is a contribution to the study of the effects of experimental lumbar "lesions." "Lesions" were produced by forcible subluxation in which it is amusing to note that great care was taken to prevent any injury to the articular tissues. "Lesions" were also produced by gentle taps near the spinous processes of the selected vertebrae. These animals were then studied. So far as one can judge from the decidedly imperfect x-rays reproduced as evidence, a partial fracture of the spine was not uncommon. Various organs were then studied with regard to the effect of these lesions, but the work seems loose and very discursive, and is far from convincing. In this experimental work two especially long steps are taken by making assumptions which will demand better proof before animal experimentation can be of value. These assumptions are: (1) The frequency of osteopathic lesions of a demonstrable character existing in human beings. (2) That such lesions can be duplicated in quadrupeds by wrenching, tapping and manipulating their spines.

My practical experience with osteopathy is not small nor in any way unprejudiced, but is, nevertheless, perhaps worth mentioning. At least half or two-thirds of the patients who consult me have been first under treatment by osteopathy. These, of course, represent the unsuccessful cases, and conclusions drawn from an analysis of them may not be fair, and I presume that a good many of my own failures drift into the hands of the osteopath, but in analyzing the method pursued by them in the cases alluded to, I have not drawn very favorable conclusions as to their efficiency or reasonableness in a fair proportion of the cases. For example, to assume that the disability of poliomyelitis arises from a lesion of the vertebral column is manifestly fantastic and not

supported by the slightest evidence. And the treatment of this disease, based on the theory that improving the circulation in the cord is going to do any good, is decidedly unreasonable and very detrimental to the patient in wasting time in the early stages of the disease when reasonable therapeutic measures might accomplish much.

The information given above regarding osteopathy has been derived from a study of books, not to be found in the Boston Public Library, the Boston Medical Library, or the Library of the Harvard Medical School, a condition which seems unfortunate. Nothing, I believe, would do more to discredit the present osteopathy than to make its literature available to medical men and to the more intelligent public.

There are said to be 5,000 to 6,000 osteopaths in the United States. They are registered and practise in forty-two states. In Massachusetts they take the same examination as that required for registration in medicine, and in the eyes of the law possess the same qualifications as regularly educated physicians. Osteopaths who were in practice at the time the registration law went into effect were licensed to practise without examination.

With regard to bone-setting³¹ and osteopathy there can be no question that rough manipulation may cure some cases where gentler methods have not succeeded, but at the same time³¹ in many cases cured by the bone-setter, relief might have been afforded by prolonged massage, etc., over a longer period. Apparently bone-setting is most successful in traumatic affections of the joints and spine where recovery has been delayed by adhesions and stiffness.

The unqualified bone-setter in general says that the joint is "out" and that he reduces it. The osteopath says that there is a "lesion" and that he "adjusts" it. The latter adds to bone-setting the explanation of infections and most other diseases by assuming spinal lesions which in an unexplained way affect the system.

Sir Jas. Paget advised the profession in 1867 to "copy what is good in the practice of bone-setters," but manipulative treatment has been and is still neglected, and overlooked by the medical schools and the surgeons, and we cannot, and must not, shut our eyes to the fact that bone-setting is at times effective where the routine surgical measures fail, and that osteopathy is only modified bone-setting.

Chiropractic.—When we come to the third and youngest, and least reputable of the three manipulative sisters, Chiropractic, we take a definite step downward. *The Journal of Osteopathy* speaks of chiropractors as "fakers."³² but the Supreme Court, of Montana, handed down a decision that "chiropractic is nothing

more nor less than osteopathy under another name."³³

Chiropractic was "discovered" in 1895 by Mr. D. D. Palmer,³⁴ who had had some experience as an unsuccessful magnetic healer, in the following way, as related by his son, J. J. Palmer.³⁵ "Harvey Lillard was a janitor in the building in which father had his office at the time, in the Ryan block at Davenport, Iowa. Harvey came in one day thoroughly deaf. Father asked him how long he had been deaf, and he told him seventeen years. Father said, 'How did this occur?' Harvey said, 'I was in a stooped, cramped position, and while in that position I felt something pop, and heard it crack in my back.' Father looked him over, laid him down on the cot, and there was a great subluxation on the back. Harvey said he went deaf within two minutes after that popping occurred in the spine, and had been deaf ever since, seventeen years. Father reasoned out the fundamental thought of this thing, which was that if something went wrong in that back and caused deafness, the reduction of that subluxation should cure it. That bump was adjusted, was reduced, and within ten minutes Harvey had his hearing, and has had it ever since."

In this simple way Chiropractic was born. With regard to this birth of Chiropractic, an amusing incident occurred in the trial at which Mr. Palmer testified. He was asked whether his father did not give birth to Chiropractic. He gave a negative answer, stating that his father, not being an obstetrician, could not give birth to Chiropractic. Mr. Palmer seems to have confused in his mind the relative function of the obstetrician and the mother in labor, and seems to have the idea that it is the obstetrician, and not the mother, who gives birth to the child.³⁶ Mr. D. D. Palmer was later succeeded by his son, Mr. J. J. Palmer, the present head of the Palmer School of Chiropractic (the mother school), to be described later. The junior Mr. Palmer received a grade school education, and at the age of 11, being "kicked from home," as he expressed it in Court, was a practitioner at the age of 12. He subsequently took the degree of D. C. from his father's school and still later received the honorary degree of Ph.C. from the faculty of the same school, of which faculty of eight his wife was a member.

The basis of the so-called "science" is the so-called "chiropractic subluxation" of a vertebra. This means a slight or partial separation between the articulations so that they are not exactly together. When a subluxation occurs there begins a pressure on the nerve coming thru the intervertebral foramina and this shuts off the flow of life force going thru that nerve and acts as a rheostat or booster to the cur-

rent going through it. Chiropractically speaking, disease is simply a register as to the amount or excess of current that an organ receives at the end of the nerve: Slight pressure "steps up" the current; heavy pressure paralyzes. One would, therefore, adjust for cancer or gonorrhoea.

This theory of disease is too fantastic, crude and unsupported to warrant discussion, but it spells danger to the community and to what lengths it will go can only be appreciated by reading the testimony of B. J. Palmer in the Wisconsin courts.³⁷

One passes next to the feature which is most prominent in the chiropractic advertisements: that is to say, the commercial side of the science. As an instance of the chiropractic attitude, the following figures (no source quoted), are taken from the *Metropolitan Magazine*³⁸ advertising section. "The following statistics of the 1818 influenza epidemic are respectively submitted: one out of every sixteen patients died under medical treatment; one out of twenty-seven under osteopathic treatment; one out of 513 under Christian Science; one out of every 886 patients under chiropractic adjustment." This advertisement is put out under the name of the Universal Chiropractic Association, Davenport, Iowa. It is interesting to note that this town is the headquarters of the Palmer School, which will be spoken of presently.

Another advertisement speaks of chiropractic as "the great modern school of healing physical ills," and goes on further to state that "the hand which does the work must be trained and skilled, and guided by the well-trained brain of the chiropractor. The use of the hand alone is not sufficient; the head must back it up, guide and direct its progress." This startling statement, that it is necessary to use the head, is derived from the annual announcement of the American University, chartered by the State of Illinois, and located in Chicago.

It may be interesting to show along what lines this university proposes to teach the scientific basis of chiropractic. The home study course of the university confers the degree of D. C., Doctor of Chiropractic. It is gratifying to note that the course is "the most complete, most concise, and most practical ever prepared." The complete course comprises 16 sections, each section contains from 3 to 5 lessons—65 lessons in all.

In addition to the instruction which is placed at \$105 for the entire course (reduced for cash), the student receives absolutely free a full set of eight large anatomical and physiological charts, regularly valued at \$15, a bound manual which furnishes a complete guide to them; and a complete set of four regional comparative graphs, whatever these may be; a set of 150 illustrative spinal columns; a complete set of

five colored nerve pain area and commusion charts, worth \$16.50. To poor, but deserving students, the following equipment is also given free upon payment of the enrolment fee: one urine test case and set; one stethoscope; one nickel-plated tongue depressor; one metal pleximeter; one tested clinical thermometer; one genuine Flint pattern percussion hammer; one illustrated text-book on the Theory and Practice of Osteopathy; one De Luxe Dictionary of 1,000 pages; one magnificent complete set of eight grouped lithographed anatomical and physiological charts; one bound manual. Their generosity does not, however, stop here, for, at the completion of the course, the regular University diploma is conferred without extra charge upon the students with the degree of Doctor of Chiropractic; and, in order to give the graduate "the right start," 100 adjustment cards, "which you give to patients," and "1000 pamphlets with your name and address printed on them, which tell prospective patients all about chiropractic," are also given free. According to the prospectus, "this advertising material will bring you into prominence and should quickly crowd your office with patients."

Each student is obliged to sign an agreement: "I hereby agree to hold all instructions and information, which I receive from you in absolute confidence, and will not permit others to see the lessons or to study the course."

The requirements for admission to this course are surprisingly simple. "Any man or woman of average intelligence, who has a common school education, may acquire a thorough, complete, and efficient knowledge, in the art and science of chiropractic by means of the instruction" given in this course. All that is required on the part of the student is "a conscientious persevering study of the lessons, and a faithful observance of the rules and practice given therein." "Many elderly persons have taken up the profession and have done well with it." The age advised for beginning the course is 21 years for men and 18 or more for women; but many students and graduates are over 50, and certain students over 60 have done most excellent work.

Another advantage of the course offered is that the student is able to practise his profession during the course. It is not stated at what period of instruction one becomes proficient, but students are often able to make money while they are learning. For example, Dr. B. earned over \$200 while taking the course, and Dr. D. made from \$3 to \$5 every day while studying. After 10 weeks' study, Dr. S. could earn \$35 a week.

It is, therefore, evident that as a financial proposition, as exemplified in this course, chiropractic offers very great inducements. The only thing which it is difficult to understand is that an institution which offers such great

financial advantages should need to take such pains to secure students. Late in September, 1919, an advertisement was published, offering for nothing, anatomical charts, estimated at a fairly high value. A woman, who was interested to see where the catch was, wrote a letter, asking how these might be obtained. She was informed that these charts were given when the enrolment fee was received, and she has since received from the University a succession of letters up to date, the first being in October, 1919, and the last one in January, 1922. After the first one or two, the letters are addressed "Dear Friend:" and suggest that they are form letters. They have also come with a curious regularity, and from the 1st to the 15th of the month in October, November, December, 1919; January, February, March, April, May, and November, 1920, and January, 1922. During this time she has received 10 enrolment blanks, the annual catalog of the University, a pamphlet, "The Great Profession for Women," and a large number of miscellaneous circulars.

This course apparently corresponds to the cheap medical school now driven out of existence; but as a chain is no stronger than its weakest link, the chiropractor need be no better than that pictured in the foregoing description.

Further light is, however, thrown on the subject of chiropractic education and principles, by Dr. George Dock, of St. Louis, in an admirable account²⁰ of his visit to the mother school, already referred to, which may presumably be taken as representing their highest standards. The following comment of his must be taken seriously: "It is true, in a sense, that the method of study followed, and the methods of practice, inculcated are not worth the consideration of intelligent people; yet the fact that more than 3,000 potential voters spend a number of months and several hundred dollars apiece in getting the so-called training in a single school is a matter worth the consideration, not only of physicians, but also of hygienists, economists, psychologists and jurists."

The guide explained the theory of chiropractic to Dr. Dock "by means of the narrowed feramina in the scoliotic specimens, showing how the "vital force" that should go through the nerves has difficulties. He also talked much about the "innate mind," which he was confident was wholly independent of the body."

The chief method of treatment, and the one to which a large amount of the student's time is devoted, is the "chiropractic thrust." Form is acquired by practice on "pieces of gas-pipe with a cap on top and a fairly strong spring inside. . . . The 'thrust' is a quick spontane-

ous push with the heel of the hand upon the bony process of misaligned vertebrae."

Dr. Dock describes the method of treatment as follows: "The patient lying down, a rapid palpation is sometimes made, very often, in fact, none at all, as the site to be treated is already known; then the left hand is arranged for the thrust, the other hand fastened around the wrist, and a rapid push downward is made, the whole thing taking much less time than it takes to describe. A girl student sitting next to me, who said she had often been adjusted, said the palpation and thrust had no particular local effect, such as tickling. Those who imagine that the treatment is used only for local diseases should hear the recommendation of the effects in general malaise, as from being up too late at night: the value of the treatment for workmen, and its use in blindness, deafness, cancer of the stomach and liver, smallpox, measles, influenza, etc." So much for the educational side.

Leslie's Weekly states that, from their own figures, chiropractic practitioners number 10,000 in the United States, with nearly 1,000,000 patients, who contribute to their coffers between \$50,000,000 and \$60,000,000 annually;⁴⁰ and a prominent doctor of chiropractic recently stated that there was a demand for 100,000 chiropractors in this country today.⁴¹

Leslie's Weekly speaks of a chiropractor, who was formerly a carpenter and who, last year, made \$8,000 in his business.⁴² Another chiropractor,⁴³ in Illinois, was 32 years old when he took "the science" up. Lack of education, amongst other things, had held him back. He had to borrow about \$400 to get through school. In addition to relieving a great deal of suffering, which must have been a remarkable satisfaction to him, he has saved money. He has three automobiles, not Fords, owns real estate to the value of \$7,000 to \$8,000, and pays income taxes.

Another gentleman, no longer young, but 72 years old, this year, is apparently finding his practice interesting, and it runs from \$700 to over \$1,000 a month.

Leslie's Weekly quotes a keen observer of chiropractic as follows: "This is certainly wonderful business, this chiropractic; I have seen enough. I am going to take a course and practise. I can do it on the side in addition to my restaurant business."

"Acres of diamonds and notions of gold are promised to the sober and industrious young chiropractor in a pamphlet issued by the New York College of Chiropractic. . . . And the beauty of it is," continues the pamphlet, "that here it is assured without the hardships and the strain of mining towns."⁴⁴

Moreover, to judge from the testimonials,

chiropractic seems particularly suited as a profession for old and broken down men, and for those unable to get anything else to do.

Chiropractors claim that they are licensed to practise in 22 states. The Universal Chiropractors' Association guarantees the graduate "the legal right to practise; or we will, thru orness of the law, know the reason why. . . . The fact that chiropractors are practising in every state in the Union, and that the U. C. A. has not failed to protect them speaks for itself."⁴⁵

In Massachusetts they have no standing whatever. The escape for the chiropractic in this state is to register as a masseur, but to pose as a chiropractor. If he is caught, he has only to claim that he is practising massage. It seems not unlikely that a definite attempt will be made in this state to establish a licensing board for chiropractic.

5. *The Amateur Quack*.—The last and fifth division of the irregular practitioner has not been, up to this time, sufficiently appreciated. The amateur quacks out-number all the others put together. They are active in every community. They are actuated by altruistic motives and they do only a moderate amount of harm. The prevalence of these amateurs in medical matters is not new.

"It is related that Alfonso D'Este, Duke of Ferrara, one day in conversation wondered what trade or profession was most common. His fool, Gonelle, at once said that the art of medicine had the largest number of professors, and wagered that he would prove his assertion within twenty-four hours. The next morning, Gonelle came out of his dwelling, his head swathed in wrappings, his hat crushed down upon his head, and his shoulders huddled up under his cloak. The first man he met asked him what was the matter. He answered: "I have a frightful toothache." "Ah, my friend," said the other, "I know the best cure for that," and told him of it. Gonelle wrote his name on his tablet, pretending also to make a note of the recipe. The whole length of the street he met no one who did not tell him some cure or other, all different from the rest, but declared to have been thoroughly tried and to be infallible in its operation. On reaching the courtyard of the palace he found himself surrounded by people who were also eager in offering advice. Their names also went down on his tablets. When he entered the Duke's chamber His Excellency at once called out, "What is the matter, Gonelle?" The fool answered that he had a toothache; whereupon the Duke said, "I know something that will stop the pain at once, even if the tooth is decayed. Messer Antonio Mussa Brassavalo, my physician, has never ordered anything better. Do this, and that, and at once you will be cured."

Gonelle then threw off his wrappings and exclaimed, "You, too, my lord, are a doctor. I have already on my way hither, although I had to pass along only one street, found more than two hundred others. Here is the list. I am ready to bet that I should find more than ten thousand if I went all about the town. Can you find more people practising any profession?"⁷⁴⁶

If any one of you will do your knee up in a ham splint and bandage, and take a pair of crutches and go three or four miles in the trolley cars, you will find out two things:

(1) The desire of everybody to be considerate and to make room for the invalid to sit down.

(2) The curiosity, un concealed, but outspoken, of many of your fellow passengers as to the cause, history, and progress of the ailment. People who have never heard of Mr. Howells' well-known man, in Chicago, who made his fortune by minding his own business, are eager to offer advice. You may give them whatever diagnosis you like, varying from a sprained knee to sarcoma, or fractured patella, and you will find that they have either had it themselves, or had a relative or friend who had it, and the treatment by which he was cured was something entirely different from yours, unless the result was fatal, in which case you will be informed of that. The number of remedies proposed is legion and it is surprising to find that more people are not unsettled by this sort of thing.

This form of irregularity requires no legislation. It has always existed and it always will, for this tendency represents an inherent quality in human nature; the desire to give advice.

Conclusion.—We are, it seems to me, too prone to regard the irregular practice of our own day and in our own community as a particular misfortune and an unprecedented folly on the part of the public. For that reason I have tried to show that irregular practice has always been and probably always will be with us in varying form, but that in general it follows well-defined channels, inasmuch as it rests on an inherent tendency in the human race to believe in the wonderful, the mystical, the obscure, the new, the unusual and the irregular. There are hundreds of men all over the country, waiting to buy gold bricks or to entrust a roll of bills to a stranger while he goes to the bank for more.

Today Christian Science and manipulative methods hold the centre of the stage; if they were wiped out, some other form of irregular healing would take their place. Christian Science developed under a wonderful woman, who understood advertising and business matters in a very practical way; but she is dead and her successors are quarreling.

Osteopathy is in reality bone-setting with a pseudo-scientific explanation superimposed, but chiropractic seems merely a cheap commercial enterprise, modelled on osteopathy—too successful, growing too fast, and too self-confident to endure permanently, although at present it is a real menace to the health of the community.

The present situation should not be taken too seriously in view of the history of the past, nor too lightly in view of the public health of the future. Our attitude as a profession has been to shut our eyes to these cults, to denounce them in general terms, and to restrict them as much as possible. But that is not the way that nostrums were so effectively restricted in the campaign a few years ago. There, instead of condemning them in general terms as had been done previously, the terms were specific; each nostrum was analyzed and the analysis given full publicity. It was shown that alcohol, morphia and cocaine were being distributed under false pretences, and so general was the publicity that legislation of an effectual character was compelled.

Miracle healing and mental healing, when associated in any way with religious belief, cannot be argued about, and may only be restricted to the extent of preserving the health of the community and safeguarding so far as possible the avoidable deaths of innocent persons at the hands of religious fanatics.

With regard to manipulative methods, we should, it seems to me, adopt a definite course of action toward the present condition, already begun by the *Journal of the American Medical Association*, and instead of excluding the literature of irregular cults from our libraries, we should, I believe, give it the widest publicity and encourage students and practitioners to familiarize themselves with it. Nothing can be more detrimental to absurd claims than a free and general knowledge of their literature. Those in doubt about chiropractic need only to read the testimony of Palmer before the Wisconsin courts to realize how slender is the scaffolding on which chiropractic rests, a "science" which has a school of 2000 to 3000 students.

Secondly, we should, I believe, teach our medical students the principles of physical therapeutics, and show them why manipulative methods are at times beneficial. In order to do this we should investigate these manipulative methods ourselves. The average practitioner of today condemns and deprecates these manipulative cults, but without sufficient knowledge of what they really are to make his condemnation effective. This method has proved unsuccessful and unsatisfactory in restraining them. Let us, therefore, attempt to inform the practitioner, the student and the public as to the bases as well as the claims and pretences

of these cults, and finally let us return, in closing, to the comforting statement that you can't fool all the people all the time.

GUMMATOUS CERVICAL ADENITIS.*

By WM. PEARCE COUES, M.D., BOSTON.

GUMMATOUS cervical adenitis is one of the most uncommon manifestations of syphilis, as are all gummatous infiltrations of the superficial lymph glands. According to Fasal¹ the credit of the first description of gummatous lymph glands belongs to Potier² of France, who wrote on the subject in 1842. Salneuve,³ Sarrhos,⁴ and Cahen,⁵ followed with articles in the fifties, and a number of papers had been written on the subject of this rare manifestation when Fasal's classic article appeared in the German *Archives for Dermatology and Syphilis* for 1910. This, and the article by Wile,⁶ in the same *Archives*, published in 1912, give the best account of the condition in the present literature. Fasal's article deals with gummatous lymphoma in general, while Wile's paper is on gummata of the superficial lymph glands.

American literature recorded two articles on the subject up to 1912, and most of the very recent textbooks, devoted entirely to syphilis,

either give very brief mention of the condition or do not speak of it at all.

Wile estimated that at the time of his article, the number of reported cases of gummata of the superficial lymph glands was well under one hundred.

The condition is of interest to the surgeon as well as the syphilologist. In hospital practice, the cases are apt to find their way into the surgical out-patient department, rather than into the dermatological or syphilis department. The cases are apt to be confused with tuberculous of the cervical lymph glands, with Hodgkin's disease, and with lymphosarcoma. All those who have studied the subject agree as to the extreme difficulty of making a diagnosis by microscopic examination. This is especially so in regard to tuberculosis. McLeod⁷ says: "The differentiation by the microscope between the granulomata of syphilis and tuberculosis is always difficult and sometimes impossible; for example, in syphilitic gummata, where a histological architecture may be present which resembles that of a lupus nodule in every detail with the exception of the presence of tubercle bacilli."

The histological side of the subject, Fasal tells us, has been studied by Cornil, in 1878, who wrote of the different histological appearances in the glands affected in tertiary syphilis and in primary and secondary syphilis. He found a general hyperplasia of the gland substance and a hyperplasia of the endothelial cells. Lustgarten⁸ has given the most perfect clinical description of this condition that has been written. He described the clinical appearance of the glands as the seat of gummatous inflammation. He found that the inguinal glands are the most commonly affected, and next, the cervical glands. They vary in size from a cherry to an orange, the general rule being that they are walnut size. There is seldom pain associated with the swellings. The skin over the glands may become adherent, reddened, and, finally, the gland may rupture by a tiny opening, which enlarges, and in time a typical gummatous ulcer develops.

Ramage¹⁰ wrote on the subject of gummatous adenitis in his Paris Thesis in 1880. His conclusions were as follows: Gummatous degeneration of lymphatic glands is a rare manifestation of tertiary syphilis. It most often appears one year after the primary infection. It occurs in conjunction with other tertiary manifestations, or may occur as an isolated phenomenon. As a rule, only a few glands are affected, seldom more than three. He places the incidence of the swellings in the same order as Lustgarten: first, inguinal, then sub-maxillary, and then other cervical glands. The diagnosis is often made with the greatest difficulty. The tumors must be differentiated from gummas of the skin and of the adjacent muscles, as well

*Read at a meeting of the Out Patient Staff of the Massachusetts General Hospital, March 29, 1922.

as from the satellite gland of a primary lesion. Also, there is difficulty in differentiating the glands from those affected by malignant disease. He believes the prognosis as to complete cure of the lesion good. The treatment must be both local and general.

From a study of the literature of the subject, it would seem that a number of former great syphilographers had written of the condition, and it was their conclusion that this was a rare but perfectly definite manifestation of syphilis, which clinically responded to the therapeutic test in a manner as to leave no doubt as to the diagnosis.

Virchow¹¹ mentions an early leucocytosis, and later a progressive anaemia, during the course of the trouble. He distinguished three stages in the inflammatory condition of the glands. First, the stage of simple irritation, during which the intercellular substance maintains a gelatinous consistency; second, a medullary stage, during which there is active cell proliferation, puriform softening of the tumor mass, and softening of the intercellular substance; third, the stage of caseation, in which active cell proliferation becomes less marked, but in which the main cell types are connective tissue and granulation cells.

Fasal examined gland fragments from his cases, and in one there was the picture of endarteritis obliterans, which he regarded as very suggestive as to the character of the process. Löwenbach¹² thought that at times the histologic picture could not be differentiated from that of some forms of sarcoma.

At the present time, doubt has been expressed by pathologists and clinicians as to the true location of these swellings, the thought being that they are perhaps in muscles near or around glands, or gummatous swellings over the glands, fascia, or skin. The absence of the treponema from most tertiary lesions leaves microscopic proof of the cause of the swellings wanting also. It is necessary to judge the matter broadly, and all that can be said is that the neck masses look like enlarged glands, feel like them, and have totally disappeared under specific treatment. In this connection it is fitting to remember the great controversy between Fournier and Charcot concerning the etiology of tabes, Fournier proving on purely clinical grounds, from his vast experience with thousands of syphilitics, that where there was no syphilis, there was no tabes,—a fact that was the triumph of pure clinical deduction, from a master of the subject.

The following case is the fifth I have recorded, which clinically came under this head, the other being recorded in the *Boston Medical and Surgical Journal* for November 8, 1915.¹³

E. L. F., male, 33. Married, with two chil-

dren. Was seen in the Surgical Out-Patient Department of the Massachusetts General Hospital on February 1, 1922. There was a history of a penile lesion five years previously, but the patient gave no history of having noticed any secondary symptoms. Has been well and at work. Three months ago he noticed swelling under the jaw, and then on the right side of the neck, behind the ear. The swellings gradually increased in size and the one on the right side became somewhat reddened; no pain or discomfort, however, was noticed.

Examination showed a well-developed and nourished man. The pupils were slightly oval and stiff, reacting to light and distance, however. Station was good and the knee-jerks were present. The tongue was rough, and near geographical. Mouth clean; no leukoplakia noted.

On the left side of the neck, in the submaxillary region, was a firm, non-tender mass, the size of a lemon, clinically having the appearance of a considerably enlarged lymph gland. The mass was not fixed or tender to palpation, the skin was not reddened or adherent over it.

On the right side of the neck was a mass, posterior to the upper third of the sternocleidomastoid. This was somewhat reddened, not boggy, not tender and not adherent. There was no glandular enlargement noted elsewhere. The Wassermann reaction was strongly positive. A blood smear was negative for leukemia.

The patient was transferred to the South Medical Department of the Hospital. In one week's time there was considerable improvement in the swelling of the neck. The case was regarded as probably one of gummatous cervical adenitis, with a realization that the reaction to later treatment would perhaps be the criterion as to the probable correctness of the diagnosis.

In those cases of this condition which I have seen, with few exceptions the patients have been well-nourished, the masses have been painless, and clinical signs of tuberculosis have been conspicuous by their absence; but in certain cases it is possible there is a relation between the two conditions.

Wile's⁶ case is of much interest, inasmuch as the treponema were recovered from the gland and demonstrated by the dark field. The patient, a young man 19 years of age, had received his primary infection (penile) some five months before. While receiving large doses of mercury at this time, the glands on the left side of the neck began to swell rapidly. The record stated that a "left supra-clavicular gland was enlarged to the size of a plum; it was readily movable under the skin, which was somewhat reddened over it. The gland was somewhat fluctuant. A somewhat smaller tumor, involving the lowest of the posterior cervical chain, was seen behind the sterno-mastoid muscle. The skin was reddened and the gland fluct-

minated. The uppermost gland of the posterior cervical chain and that over the mastoid process were both enlarged to the size of an olive, firm, elastic, and not fluctuating, and the skin covering them showed no change. On November 11, 1911, the largest of these four tumors, the supraclavicular, was punctured with a fine hypodermic needle and a few drops of sero-purulent fluid were aspirated with a syringe. With the aid of the dark field illumination, a few typical spirochetes were found. On the 17th of November both of the larger, fluctuating glands ruptured through pin-point openings, which rapidly enlarged until they took on the appearance of typical punched-out gummatous ulcers of the skin from which a thin sero-purulent exudate was discharged. Rapid healing took place under salvarsan, though it was not complete at time of writing, one month after treatment."

It would seem that in this case the diagnosis was certain, but the hypererithelial will no doubt say that the supposed glands were in reality not cervical lymph nodes. The distinction, however, of the actual tissue invaded is rather of academic than of practical interest, the fact of importance being that these masses in the neck, due to syphilis, are not infrequently unrecognized as such, with resulting misfortune to the patient and chagrin to the physician.

Where there are also undoubted signs of syphilis, and a positive Wassermann reaction, the nature of the enlargements in the neck region is sometimes suspected, but with negative blood, and no signs, and often no history of syphilis, the condition is most baffling, and judgment must be by the therapeutic test, the application of which will often richly repay the physician.

MEMBERSHIP CHANGES IN THE MASSACHUSETTS MEDICAL SOCIETY FOR THE MONTH OF JUNE, 1922.

OFFICIAL LIST (5TH).

Compiled by the Secretary of the Society.

ALPHABETICAL LIST.

Adler, Herman M., Chicago, Ill., now 721 South Wood St.
 Allan, Arthur Wilburn, transferred by Council from Norfolk to Suffolk.

Armstrong, Donald Budd. Resignation accepted by Council.
 Barach, Alvan Leroy. Resignation accepted by Council.
 Bell, James Francis, Jr. Resignation accepted by Council.
 1909 (Blanchard, William Herbert, Boston, 1069 1922) Boylston St.
 Restored by the Council, June 13, 1922.
 Borden, George E., from Adamsville, R. I. (non-resident), to Fall River, 132 Franklin St. (Bristol South).
 Butler, David Mathew. Resignation accepted by Council.
 Cameron, Isabella L., Minneapolis, Minn., Woman's Maternity Hospital.
 Cleaves, Helen Taft, from Palmer to Pacific Grove, Calif., 149 8th St.
 Constans, Frank Elmore, died at Brockton, May 29, 1922, aged 55.
 Crawford, Francis Xavier. Transferred by Council from Middlesex South to Suffolk.
 Dearborn, George Van Ness. Resignation accepted by Council.
 De Lue, Frederick S. Office now Boston, 84 Commonwealth Ave.
 Dolan, William Francis, from Brookline (Norfolk), to Brighton (Middlesex South). Office, Boston, 430 Marlboro St.
 Eaton, Henry Douglas. Resignation accepted by Council.
 Elliott, Russell D., Boston, now 9 Dwight St.
 Finnegan, Francis A., from Worcester (Worcester), to Lowell, 491 Lawrence St. (Middlesex North).
 Flett, Penelope McN., from East Gardner to Wakefield, 76 West Chestnut St. (Middlesex East).
 French, Leland M., from Worcester to Pittsfield, South Street Apartments (Berkshire).
 Fuller, Andrew H., from Fiskeale (Worcester), to Templeton (Worcester North).
 Gervais, Harriet Marion, now Higgin, Harriet M. Gervais, Alston. Office, Boston, State House, Div. Child Guardianship.
 Gordon, Louis, Boston, now 20 Charlesgate West.
 Gurjian, Leon K., Worcester, now 204 Main St.
 Haines, Samuel F., from Boston to Rochester, Minnesota, 711 7th St., S. W.
 Hall, William Dudley, Boston. On retired list by action of Council.
 Handy, Harry Tucker, transferred by Council from Plymouth to Norfolk South.
 Hebbard, Ellery Cola, Boston. On retired list by action of Council.
 Heffernan, David A., Boston, now 270 Commonwealth Ave.
 Hodgdon, Frank Wellington, Jr. Resignation accepted by Council.
 Janjigian, Robert Rupen. Resignation accepted by Council.
 Jeralian, Hairabed S. Resignation accepted by Council.
 Jenkins, Charles Edwin, Boston. On retired list by action of Council.
 Jones, Chester Morse, transferred by Council from Middlesex South to Suffolk.
 Keown, James Archibald. Resignation accepted by Council.
 Kline, George Lyman. Resignation accepted by Council.
 Lancey, Clifford S., from Charlton (Worcester), to Gardner, Gardner Trust Bldg. (Worcester North).
 McLaughlin, Arthur Otis, died at Haverhill, June 18, 1922, aged 42.
 Marney, Samuel L., Chelsea, now 254 Washington Ave.
 Meaker, Samuel Raynor, transferred by Council from Norfolk to Suffolk.
 Moir, Marguerite Winifred, transferred by Council from Norfolk to Suffolk.

Nichols, Edward Hall, died at his home in Boston, June 12, 1922, aged 58.
 Norton, Eben Carver, Norwood, now 38 Cottage St. Parris, Roland Oliver, transferred by Council from Middlesex South to Suffolk.
 Pettigill, Warren Martin, from West Somerville (Middlesex South), to Lawrence, U. S. Veterans' Bureau, 21 Hampshire St. (Essex North).
 Pratt, Calvin, died at Bridgewater, June 17, 1922, aged 80.
 Sachs, Benjamin, from Beverly (Essex South), to Norwood (Norfolk), 293 Washington St.
 Siragusa, James Joseph, transferred by Council from Norfolk to Suffolk.
 Stephenson, Franklin Bache, from Claremont, Calif., to Washington, D. C., Wardman Park Hotel.
 Stelson, Frank Elliot, from Nonquitt to South Dartmouth.
 Van Doursen, George L. Lowell, now 226 Central St.
 Webster, Samuel G., from West Roxbury (Norfolk), to Newtonville (Middlesex South), 15 Rossmore St.
 Weyer, Russell F., from Boston to Detroit, Mich., 1229 David Whitney Bldg.
 Wood Nelson Merwin, transferred by Council from Norfolk to Suffolk.

ADDRESSES UNKNOWN.

Azadian, David George, (Not in Fresno, Calif.)
 Lawlor, John Charles.
 McClintock, Elsie.

Changes of address should be sent to the Secretary, Dr. Walter L. Burrage, 42 Elliot Street, Jamaica Plain, 30.

NEW FELLOWS ADMITTED FOLLOWING THE EXAMINATIONS OF MAY 4, 1922, WITH THEIR ADDRESSES.

A
 Albert, Lionel Louis, Central Falls, R. I.
B
 Bacon, Gorham, Barnstable.
 Address, Yarmouthport.
 Barstow, Carl Elijah, Everett, 519 Broadway.
 Bassett, Alice Haley, Boston.
 Berkowitz, Arthur, Roxbury, 2 Hitchings St.
 Biddle, Stephen Mulford, Cambridge.
 Blackett, Charles Wesley, West Newton, Office, Rose Jr., 35 Bay State Rd.
 Bliss, William Everett, Medford, 168 Forest St.
 Bogusz-Wrazlo, Ladislaws, Cambridge, Office, Boston, 220 Hanover St.
 Boland, Benedict Fenwick, Boston.
 Boston City Hospital.
 Braverman, Aaron Henry, Lowell.
 105 Chelmsford St.
 Buckman, Thomas Ellwood, Boston.
 Boston City Hospital.
 Bunce, James Walter, North Adams, 332 Main St.
C
 Campbell, Kieher Alexander, Hopdale.
 Conins, James Brooks, Springfield, 4 Chestnut St.
 Corriden, Thomas Francis, Northampton.
 Clegg, Herbert Alexander, Lawrence, 477 Essex St.
D
 De Cicco, Luigi Marius, Fitchburg, 361 Water St.
 Downey, Hugh James, Pittsfield, 184 North St.
 Dwyer, Philip Roche, Salem, 354 Essex St.
E
 Edwards, Martin Russ, Wayland, State Rd., East.
F
 Favaloro, John, Lowell, St. John's Hospital.
 Fildstow, Marjorie, Boston, Boston City Hosp.
G
 Galland, Hia, Boston, 196 Hanover St.
 Garoyan, Gaspard, Boston, 117 Mass. Ave.

Glickman, Hélène Sarah, Springfield.
 476 Chestnut St.
 Gordon, George Korolick, Malden, 458 Main St.
H
 Haley, Paul James Dodge, Medford, 49 High St.
 Hamilton, Wallace Field, Newton, Newton Hospital.
 Hannaford, Charles, Portsmouth, N. H.
 William, 39 Pleasant St.
 Harrington, Winthrop, Worcester.
 Wendell, Worcester City Hospital.
 Hawley, Ralph Ernest, Lynn, "The Breakers."
 Dudley, Lynn Shore Drive.
 Healy, Harrison Thomas, New Bedford, 1174 Pleasant St.
J
 Jordan, Sara Murray, Brookline, 5 Babcock St.
K
 Kambertz, Samuel, Boston, 687 Boylston St.
 Klein, Alvin Walter, Stockbridge, Lee Road.
 Knowlton, James Edward, Quincy, 579 Hancock St.
 Kraus, Dorris May Presson, Framingham, P.O. Box 99.
L
 Emerson, Joseph, Roxbury, 37 Munroe St.
 Littlehale, Roy Frederic, Hanson, Plymouth County Hosp.
M
 Marble, Howard Bennett, Shelburne Falls, 63 Bridge St.
 McCormick, William, New Bedford.
 Aloysius, 28 Parker St.
 McDonald, Harry Leo, Malden, 221 Highland Ave.
 McSweeney, Joseph Henry, Somerville, 22 Bow St.
 Monette, Camille Joseph, Taunton, 453 Bay St.
 Moses, Alvin Raymond, Worcester, Worcester City Hospital.
N
 Nichols, Alvord Gates, Worcester.
 Worcester City Hospital.
 Nichols, Andrew, 3d, Hathorne (Danvers), 322 Newbury St.

The Massachusetts Medical Society.

PROCEEDINGS OF THE SOCIETY.

First Day, June 13, 1922.

CLINICS were held at the principal hospitals of Boston during the morning, according to a revised program published in the *Boston Medical and Surgical Journal*, the official organ of the Society, in its issue of June 8, 1922. The Sections of Surgery and Pediatrics held their meetings at 10 A.M. in buildings C and B, respectively, at the Harvard Medical School on Longwood avenue, Boston. At 11.30 A.M. the Supervisors held their annual meeting in Building A amphitheatre, at the school, ten Supervisors being present and the usual business transacted. At noon the Council met in the same room, one hundred and fifteen signing the two attendance books. (See Proceedings of the Council.) During the afternoon the Sections of Medicine, Tuberculosis, and Hospital Administration held their meetings at the school in Buildings C, B, and E, respectively.

The attendance and the officers elected for the next year were as follows:

SURGERY: Attendance, 150. Officers for 1923:

CHAIRMAN, J. B. Thomas, Pittsfield.

SECRETARY, G. A. Leland, Jr., Boston.

PEDIATRICS: Attendance, 90. Officers for 1923:

CHAIRMAN, A. C. Eastman, Springfield.

SECRETARY, J. H. Young, Jr., Newton.

MEDICINE: Attendance, 150. Officers for 1923:

CHAIRMAN, B. W. Paddock, Pittsfield.

SECRETARY, F. M. Rackemann, Boston.

TUBERCULOSIS: Attendance, 200. Officers for 1923:

CHAIRMAN, E. O. Ois, Boston.

SECRETARY, S. H. Renick, Reading.

HOSPITAL ADMINISTRATION: Attendance, 48. Officers for 1923:

CHAIRMAN, J. J. Dowling, Boston.

SECRETARY, E. W. Wilson, Boston.

NEW SECTION OF OBSTETRICS AND GYNECOLOGY:

CHAIRMAN, C. E. Morgan, Somerville.

SECRETARY,

In the evening the Shattuck Lecture was delivered in John Ware Hall, Boston Medical Library, by Dr. Elliott P. Joslin of Boston. Subject: "The Treatment of Diabetes Mellitus." Attendance, 300.

Second Day, June 14, 1922.

The second day of the annual meeting was begun by demonstrations and papers in the departments of physiology and pharmacology at the Harvard Medical School, as set forth in the program in the June 8 number of the *Boston Medical and Surgical Journal* and earlier in the official program, sent to all the fellows of the Society, the attendance at both being about 250. At 11.30 o'clock the Society gathered in the amphitheatre of Building C for the exercises of the one hundred and forty-first anniversary, 185 fellows and guests being present. The President, Dr. John W. Bartol of Boston,

called the meeting to order; the Secretary read the minutes of the last meeting and they were approved. The Secretary read the following statement of the membership for the year closing on that day: Deaths, 37; resignations, 41; deprived of the privileges of fellowship, 12, making a total loss of 90. There had been restored to fellowship by the Council, 7; readmitted by the censors, 5, and new fellows, 171, making a total gain of 183 and a net gain of 93. Adding this to the total membership on June 1, 1921, 3933, the total membership on June 14, 1922, was 1026.

The following proposed amendment to Chapter IV, Section 3, of the By-Laws which had been approved by the Council, February 2, 1921, and had been referred to this meeting by the Society on June 1, 1921, was read by the Chair, who also explained its purpose:

That Chapter IV, Section 3, of the By-Laws be so amended that the last sentence of paragraph one shall read: "Councilors only, shall be eligible to the offices above named," *viz.*, president, vice-president, secretary, treasurer and librarian, thus conforming the By-Laws to the Statutes, 1893, Chapter 85, Section 3, Digest, Article V, paragraph 3, which provides that the Councilors shall "appoint, from among themselves, a president, and such other officers of the said corporation as are to be so appointed."

Dr. F. B. Lund moved to adopt the amendment. The motion was seconded and so voted, there being no votes in the negative.

The President read an extract from the Proceedings of the Council of February 2, 1921, in which the Chairman of the Committee on Membership and Finance called attention to the terms of Chapter 15, Section 9, of the Statutes of 1781, now Article X of the Digest, whereby the amount of money the Society may receive from real and personal estate is limited to eight hundred pounds, the pound "to be valued in silver at six shillings and eight pence per ounce." He thought that such a sum was manifestly unsuited to the present requirements of the Society. He moved and it was voted by the Council to refer the matter to the Committee on State and National Legislation. That committee had reported to the Council yesterday, with the result that the following vote had been passed by that body:

Voted. That the Society be requested to appoint at the annual meeting a committee who shall petition the next General Court to enact an amendment of Chapter 15, Section 9, of the Statutes of 1781 so that said statute shall conform to the provisions of Chapter 180, Section 9, of the General Laws of Massachusetts, 1921, relating to charitable corporations, as regards the amount of property the Society may hold; the intention of this motion being that the proposed amendment shall be submitted for approval to the Council at its October meeting.

The Chair stated that a matter of this importance ought to have action by the Society and

that the Council should be asked its approval of any amendment that might be prepared by a committee to be appointed. He asked the Secretary to read Article X of the Digest and the following Section 9, of Chapter 180, of the General Laws of Massachusetts, 1921, having to do with corporations for charitable and certain other purposes:

"Section 9. Any corporation organized under general or special laws for any of the purposes mentioned in this chapter may hold real and personal estate to an amount not exceeding two million dollars, which shall be devoted to the purpose set forth in its charter or agreement of association, and it may receive and hold, in trust or otherwise, funds received by gift or bequest to be devoted by it to such purpose. This section shall not limit the amount of property which may be held by a corporation under the authority of any special law."

Dr. H. T. Hutchins made the following motion:

Moved, that a committee be appointed, consisting of the President and Secretary, who in conference with legal counsel shall prepare a petition to the next General Court for the enactment of an amendment to Chapter 15, Section 9, of the Statutes of 1781, to bring said section into conformity with Chapter 180, Section 9, of the General Laws of Massachusetts, 1921, relating to charitable corporations, such proposed amendment to be submitted to the Council at the October meeting for approval.

The motion, having been seconded, was passed by a unanimous vote.

Dr. F. B. Lund spoke of the proposed Gorgas Memorial Institute of Tropical and Preventive Medicine at Panama. After referring to the life, character and achievements of General Gorgas, he bespoke the interest of the medical profession in this international and humanitarian undertaking. He was followed by Dr. R. P. Strong on the same subject.

Dr. Albert Evans moved and it was *Voted*, That a committee of five be appointed by the Chair from the Fellows of the Massachusetts Medical Society to coöperate with the officers of the Gorgas Memorial Institute of Tropical and Preventive Medicine in helping raise the Gorgas Memorial Endowment Fund.

At 12.34 p. m., Dr. Kendall Emerson of Worcester delivered the annual discourse with the subject: "The International Mind in Medicine." On motion by Dr. H. O. Marey, the thanks and appreciation of the Society were voted Dr. Emerson for his oration.

During the afternoon demonstrations were given in the departments of chemistry and hygiene at the school, with a good attendance, and in the evening the annual dinner was served in the ballroom of the Copley-Plaza Hotel to 530 fellows and their guests. The speakers were His Excellency Channing H. Cox, Governor of the Commonwealth; Hon. Thomas C.

O'Brien, District Attorney for Suffolk County; Hon. Benjamin Loring Young, Speaker of the Massachusetts House of Representatives, and Samuel Williston, Dane Professor of Law in Harvard University. The President spoke of the lack of a clergyman, the Rev. W. L. Sperry being detained by illness, and to supply this lack he brought the exercises to a close with an address in which religion was adapted to present medical problems, taking as a text, Hebrews 4, 14, "Let us hold fast our profession." A detailed account of the speeches may be found in the BOSTON MEDICAL AND SURGICAL JOURNAL for June 22, 1922, pages 862-864.

Adjourned at 10.30 p. m.

WALTER L. BURRAGE,
Secretary.

ADMISSIONS REPORTED FROM JUNE 1, 1921, TO JUNE 14, 1922.

Year of Admission	Name	Residence	Medical College
1921	Adams, Frank Donnette	Boston	11
1922	Albert, Lionel Louis	Central Falls, R. I.	32
1922	Bacon, Gorham	Barnstable	10
1922	Barstow, Carl Elijah	Everett	12
1922	Bassett, Alice Haley	Boston	12
1921	Baxter, Raymond Harding	Marion	17
1921	Benedict, Mary Kendrick	Arlington Heights	6
1922	Berkowitz, Arthur	Roxbury	12
1922	Biddle, Stephen	Mutford, Cambridge	12
1922	Blackett, Charles Wesley, Jr.	West Newton	11

 J. S. Stone.....Suffolk
 A. L. Beals.....Plymouth
 W. J. Walton.....Norfolk
 L. F. Baker.....Worcester North
 W. J. Collins.....Hampshire
 P. D. McAlister.....Essex North
 G. E. Emory.....Worcester
 H. C. Allen.....Bristol South

Sumner Coolidge.....	Bristol North
M. B. Hodskins.....	Hampden
C. E. Ordway.....	Middlesex East
F. E. Jones.....	Norfolk South
G. H. Thompson.....	Berkshire
H. D. Handy.....	Barnstable

COUNCILORS 1922-1923.

ELECTED BY THE DISTRICT MEDICAL SOCIETIES AT THEIR ANNUAL MEETINGS, APRIL 15 TO MAY 15, 1922, AND THOSE WHO ARE COUNCILORS UNDER THE TERMS OF THE BY-LAWS.

NOTE.—The initials M.N.C., following the name of a councilor, indicate that he is a member of the Nominating Committee. V.P. indicates that a member is a councilor by virtue of his office as president of a district society, and so vice-president of the general society. C. indicates that he is chairman of a Standing Committee. Ex-P. indicates ex-president.

Book Reviews.

The Vitamins. By H. C. SHERMAN and S. L. SMITH. 273 pp. New York: Chemical Catalog Co. 1922.

This volume, which is one of the American Chemical Society monographs, is probably the best and most important summary of the knowledge of vitamins which has appeared. The subject is discussed in the conventional manner: an historical introduction; the antineuritic vitamin (water-soluble B); the antiscorbutic vitamin (vitamin C); the fat-soluble vitamin (vitamin A); a chapter on "Vitamins in the Problem of Food Supply," and a bibliography of about a thousand titles.

In discussing the three recognized vitamins, the authors follow a uniform plan, summariz-

ing, in order, the evidence of the existence of the vitamin; its occurrence in foods; its physiological and, so far as they are known, its physical and chemical properties. Elaborate tables are given showing the occurrence and the relative abundance of the vitamins in all of the common foods: milk, grains, meats, vegetables, etc.

This summary of present knowledge brings out forcibly the unsatisfactory state of the entire subject: while an immense amount of work has been done on the distribution of the vitamins, very little has been accomplished in determining what they are or how they act.

The authors remark in the preface that it is hoped that the present work may do something to show the true significance of the vitamins and to avoid exaggerated impressions, and, to the latter end, suggest that the non-technical reader read the last chapter ("Vitamins in the Problem of Food Supply") first. In this chapter it is stated: "Even with our present knowledge we believe it safe to say that with a dietary selected to make the best use of our ordinary staple foods there will rarely, if ever, be occasion to purchase vitamins in any other form, or to give any greater anxiety to the vitamins than to some other factors which enter into our present conception of nutritive requirements and food values." The essentials of an adequate food supply are briefly enumerated: "Sufficient amounts of digestible organic nutrients to yield the necessary number of calories of energy; enough protein of suitable sorts; adequate amounts and suitable proportions of a number of mineral or inorganic elements; and enough of each of at least three kinds of food hormones or vitamins."

Although there may be no pressing practical need for isolated vitamins, and although it is quite probable that other deficiencies in our diet are of equal or greater importance, the scientific mind will not be satisfied until the nature of these mysterious elements and their method of action are known; in fact, such knowledge is a prerequisite to a really intelligent system of dietetics.

Arterial Sclerosis. By LOUIS FAUGERES BISHOP, Oxford Medical Publications. London.

This readable book is the exposition of the author's theory of the cause of arterial sclerosis and its logical treatment. Fortunately the theory is not arguable. There is little definite proof to support it and equally little to controvert it. Therefore the author is not obliged to occupy much of the reader's time in defense of his theory,—a procedure which is seldom profitable,—and is free to discuss at length the results of treatment by his method, so that there is much of practical value in the book.

Bishop believes that arterial sclerosis is due to low-grade protein sensitization, and that the treatment consists essentially in a diet containing few kinds of protein, but not necessarily greatly restricted in amount of protein. Such a diet would certainly be better for most arterio-sclerotics than the "protein free diet" still used by many. The author believes that the best form in which to give protein is as cheese or vegetables. His chapter on cheese is interesting and enlightening.

The main value of the book, however, is that it contains a great deal of careful clinical observation and much advice concerning the details which make up so large a part of the treatment of the patient with hard arteries. Whether the theory presented can be definitely proven or not, the book is worth while because it brings home the fact that the successful treatment of arterial sclerosis is composed of moderation and such optimism as can be honestly exhibited.

Nutrition and Growth in Children. By WILLIAM R. P. EMERSON. New York: D. Appleton & Co.

Dr. Emerson has made a very interesting contribution to a problem of great importance and extraordinary complexity. He has classified children according to a scale of height and weight. By these standards he shows that from one quarter to one half of all children fall more than 7% below what he has fixed as a desirable standard.

By carefully worked out methods he brings a given group of malnourished children to a "normal" condition. The methods are clearly described and in his hands are obviously highly successful.

Without question Dr. Emerson's work is of extraordinary value and criticism is directed only at details.

Two obvious questions arise in the minds of those accustomed to dealing with masses of children. In the first place, is "malnutrition" as definite an entity as Dr. Emerson thinks it is? In the second place, is the height to weight relation with its definitely stated normal limits sufficiently accurate?

The reviewer is skeptical on both these points, but it is entirely clear that discussion involves working out an alternative? At present Dr. Emerson holds an almost impregnable position from which no one appears to be able to dislodge him, for lack of stronger weapons than doubt.

Influenza, Essays by Several Authors. Edited by F. G. CROOKSHANK, M.D. (Lond.), F.R.C.P., Physician: The Prince of Wales General Hospital, The French Hospital and Dispensary, and St. Mark's Hospital, London. Consulting Physician, New End Hospital, Hampstead. London: William Heinemann, 1922.

Dr. Crookshank, in a most scholarly collection of essays, deals with the whole conception of influenza from a broader and more analytical viewpoint than most of us, I think, are accustomed to consider it. Seven of the essays included are contributed by the editor, and in these the epidemiology, historical conceptions, and definition of Influenza are taken up.

During 500 years there have been 15 great pandemics of disease; each was considered a new disease, and many names have been given to them: "epidemic catarrhal fever," the "dengue" of a century ago, the "sweating sicknesses" of the 15th and 16th centuries; all, viewing history from a distant vantage point, are analogous to what we call "influenza." Most of these "epidemic constitutions" were preceded or followed by lesser outbreaks of encephalomyelitis or meningo-encephalomyelitis, meningitis, poliomyelitis, encephalitis, or whatever they may have been named at various times. This most variable of diseases we have attempted to classify and pigeonhole according to specificity of type and etiology, but it defies classification. As W. H. Hamer writes (p. 106), "One case of measles is, of course, very similar to another case. . . . It is far otherwise in influenza, which is ever the 'new disease' or the 'new acquaintance,' and is, by general consent, the most protean of all maladies."

To quote him further: "There follows the attempt to grasp the conception of an 'influenza constitution' in the light of all the historical evidence. 'It will be seen, then, that the facts elicited on study of the relationship between influenza and cerebro-spinal fever in the recent prevalences (*i.e.*, those of 1915-1918), or within the period of notification statistics, or on a wider view, within that covered by Hirsch's chronologies, are strikingly confirmed, if in some measure also modified and corrected, on taking a broader sweep still and pursuing inquiry, by means of the great storehouses of facts collected by Creighton, into the history of the last five centuries of the influenzas, cerebro-spinal fevers, etc., which lurk more or less disguised under such designations as sweats, agues, cerebritis, encephalitis, and typhus (cerebralis or other).'"

Dwight M. Lewis, in disussing epidemiological considerations, points out that the chief source of confusion has been the persistent way in which certain *correlated* organisms have been considered as the organisms of independent, autonomous and unrelated diseases.

Taking up the bacteriology of the disease, Robert Donaldson shows the vagueness of the term influenza, and the relatively small proportion of cases in which Pfeiffer's bacillus was demonstrated. Only the second of Koch's postulates has been adequately fulfilled by this organism.

Excellent résumés of clinical and therapeutic considerations, nervous syndromes, ocular affec-

tions, surgical aspects, complications affecting the throat, nose and ear, the skin lesions, and influenza complicating pregnancy, labour, the puerperium, the diseases of women are contributed by Abrahams, Jelliffe, McHoul, Boyd, Whale, Davis, and Bourne.

Crookshank concludes the volume with "The Theory of Influenza." We must study history and epidemiology, as well as individual cases and epidemics. To answer the questions "What is Influenza?" and "What is the Cause of Influenza?" "we must comprehend the whole nexus of circumstances and conditions involved, stretching back from the reactions of personal and bacteriological factors in respect of individual cases, through the interplay of communal and local qualities and determinants concerning epidemics, to the more remote and as yet mysterious cosmic precedents that ultimately govern and control the springs and origin of life itself, and the secular modifications and transformations that to us are appreciable as plague and pestilence: '*ex influenza caelesti*.'"

It will be well worth the while of anyone who saw the recent epidemic or who is in any way interested in infectious and epidemic disease to read this stimulating volume.

Précis de Pathologie Médicale. Par MARCEL LABBÉ ET G. VITRY. Masson et Cie, Editeurs.

This work, when completed, will consist of six volumes. At the present time only Volumes 4 and 5 are finished. The complete work is intended to be a compendium of medicine. Volume 1, infectious diseases and intoxications; Volume 2, diseases of the respiratory apparatus; Volume 3, diseases of the heart and blood vessels; Volume 6, diseases of the central nervous system.

The two volumes inspected by the reviewer are Volume 4, diseases of the blood and hematopoietic organs, and diseases of the kidney, and Volume 5, diseases of the digestive apparatus and of nutrition. If the remainder of the series proves to be as excellent as Volumes 4 and 5, the series will present a remarkably compact and complete outline of medicine. The books are written in a very easy style, and can be used by persons having a rather elementary knowledge of French, providing they have mastered medical nomenclature. Although they are presented as compendiums, they cannot be considered to be brief, as the various subjects are thoroughly covered. The system of presentation consists in the consideration of an organ, its physiology, its diseases, and the pathology. The articles are so written that they bring together and correlate all that a student should know about the particular organ. The physiology, pathology and bacteriology, and clinical laboratory methods are considered. There are even such questions as should be asked the patient in arriving at a diagnosis. Likewise, the making of physical examinations for the various

organs is discussed and very adequately illustrated.

The therapeutic notes are brief and general. Surgical treatment, when indicated, is of course not detailed. The laboratory methods are not given in detail, in every case, but suggestions as to procedures are always given. The pathological anatomy is very well discussed and fairly well illustrated, mostly in black and white, reproduced in half-tones from drawings. The illustrations are particularly well chosen, whether in regard to the illustration of pathology and parasitology, or in regard to clinical features.

The nomenclature is thoroughly reliable in regard to bacteriology, parasitology and pathology.

The six volumes make a rather lengthy work for the kind of reading the medical student is apt to do in preparation for hospital examinations and state board examinations, but the reviewer knows of no work in English which is approximately equally well done.

For practitioners in medicine and for pathologists who have a wish to correlate the clinical and pathological aspects of disease, the work is admirable. It is to be recommended without reservation to those students and practitioners who desire to keep in use their knowledge of French in very useful study.

An unfortunate feature of the books is that references to original articles are not given, in spite of the fact that many authors are quoted. In the short perusal made by the reviewer, the inability to find original articles quoted proved to be disappointing.

The alphabetical index, which we are accustomed to in American text-books, is as usual not found in these two French volumes.

The Oxford Index of Therapeutics. Edited by VICTOR E. SORAPURE, Oxford Medical Publications, Henry Frowde and Hodder and Stoughton, London, 1921.

The title of this book describes its contents. It is a small encyclopedia. It is designed for the general practitioner and is to be looked upon as a concise and handy reference volume for him to turn to. The articles, contributed by some seventy-five physicians from America and Great Britain, are termed monographs in the preface. This perhaps is misleading, as they are short, concise expositions without references which desirably avoid describing a great variety of treatments. They give a suitable method for dealing with each condition considered, though occasionally methods well recognized by some leading authorities are omitted. In some instances the subject is presented so briefly that from the text one could not adequately follow out the treatment. However, this does not detract from the value of the volume, because as an index it prevents the reader from forgetting possibilities. A very brief statement regarding

etiology and diagnosis helps clarify many of the articles.

The expositions are arranged under group headings whenever the clinical relationship is such as to justify this, such as "Gastro-intestinal conditions," but many topics not conveniently falling into these groups stand by themselves in alphabetical order. The excellent, approximately seventy-five page index at the end of the volume serves for detailed reference. The last two hundred-odd pages are given to a description of the therapeutic agents.

Like all Oxford publications, the appearance and printing of the volume are attractive and pleasing.

Nervous and Mental Diseases. Edited by PETER BASSOE, M.D. Chicago: The Year Book Publishers.

This short annual volume of well-chosen neurological reviews covers critically a large field of neurology and psychiatry. The papers abstracted and discussed are all from the literature of 1921. The principal topics taken up are: Symptomatology; The Neuroses; The Cerebrospinal Fluid and the Meninges; Diseases of the Brain; Neurosyphilis; Diseases of the Spinal Cord; Diseases of the Peripheral Nerves, and Diseases of the Endocrine Glands. There is also a section of sixty-one pages on Mental Disorders. The editor makes the reviews more interesting and instructive by adding parenthetical comments which are of great aid in properly evaluating the contributions.

Perhaps the most interesting group of papers discussed is that dealing with Epidemic or Lethargic Encephalitis. As in other fields, only the significant papers are reviewed, but they are well grouped so as to bring out the advancement in knowledge.

In the Preface the author states: "This year's literature on nervous and mental disease has been abundant. German investigators in particular have published a great deal of material which was pigeon-holed during the war. The usual profusion of colored plates is no longer seen, and the text illustrations are sometimes unsatisfactory on account of the inferiority of the paper used. Among the more important German monographs representing years of thorough clinical investigation, we may single out those by Gennerich and Nonne on a subject of perennial interest—Syphilis of the Nervous System. The French, whose work also maintained a high standard during the trying war period, have furnished new contributions of lasting value, the most noteworthy of the year dealing with paralysis agitans and the sequelae of epidemic encephalitis. Much valuable work has also been done in America."

Practical Infant Feeding. By LEWIS WEBB HILL, M.D., Junior Assistant Physician to the

Children's Hospital, Boston; Assistant in Pediatrics, Harvard Medical School. Octavo of 483 pages, illustrated. Philadelphia and London: W. B. Saunders Company, 1922.

This book is written in a conversational style, which makes it easy and interesting reading, but also tends to looseness of construction and verbosity. The author first discusses the physiology and pathology of digestion and nutrition, then takes up breast and artificial feeding, disturbances of digestion and nutrition in the bottle fed, the diarrheal diseases, indigestion in older children, the management of premature infants, and finally the diseases of nutrition and eczema. He shows a wide knowledge of pediatric literature, both American and foreign, analyzes it intelligently and utilizes his knowledge practically and judiciously. He emphasizes the importance of thinking and calculating in percentages of the various food elements, stresses the necessity of determining the etiological factor in disturbances of digestion and nutrition and basing treatment on it, and shows that babies must be fed individually, not collectively. It is very pleasing to one who was trained by Dr. Rotch and who has had a part in building up the Boston school of pediatrics to know that there is at least one young man who seems likely to carry on the teachings and uphold the traditions of this school.

It would be easy to pick flaws in this book, as in any other, and there are many points which are open to criticism. This is natural, when a book deals with a subject concerning which there are so many differences of opinion as there are about infant feeding. In general, nevertheless, little can be said, except in approval. The various subjects are taken up rationally and clearly and in every instance the reasons for treatment carefully explained. The chapter on the disturbances of digestion and nutrition in the bottle fed is especially good. We wish that we could be as optimistic regarding the results of the treatment of eczema in infancy as is the author.

The practitioner and student who is willing to think and to be taught how to think will find this work most helpful and most inspiring. The man who wishes to be told how to feed all babies by rule of thumb and how to treat all disturbances of digestion and nutrition with drugs will be disappointed.

Management of the Sick Infant. By LANGLEY PORTER and WILLIAM E. CARTER. St. Louis: C. V. Mosby & Co.

In some ways this book is excellent, in others it is disappointing.

The first ten chapters are devoted to a discussion of symptoms, such as vomiting, fever, hemorrhage, etc. These chapters, with the exception of those on diarrhea and nutrition, can-

not be said to be valuable or interesting, and as is the usual case, a catalogue of all the causes of vomiting, fever or cough, makes rather hard reading.

The next ten chapters are devoted to diseases of the various organs, the next two to technique of methods of diagnosis and treatment, such as lumbar puncture, etc., and to food recipes. The last two chapters take up prescriptions for use in infancy, and the treatment of various forms of poisoning.

The chapter on methods is very good, and the excellent illustrations supplement in a graphic way the descriptions.

For the most part the chapters on treatment are sound, and full of common-sense procedures that the authors have employed. One cannot quite agree with them, however, that the "treatment of erysipelas in infancy is thoroughly satisfactory." Neither would most pediatricists be of the opinion that the serum treatment of infectious diarrhea in infancy is specific, or that the treatment of bronchial asthma with vaccines made from the stools was advisable.

The book is poorly arranged and makes hard reading on account of the headings that are used; there are too many black faced type headings scattered through the text; instead of making the subject matter clearer, this tends to irritate the reader. Despite these defects there is much that is new in the book; one feels that it is based on a large personal experience, as it undoubtedly is, and the discussions of many of the diseases considered, especially pneumonia, pyelitis and tuberculosis, are excellent.

The portions devoted to treatment are intensely practical, and for the most part sound, and the reviewer cannot help but feel that the book would have been a great deal better if the authors had confined themselves to this, instead of mixing in so much other material.

The Healthy Child from Two to Seven. By FRANCIS HAMILTON MACCARTHY. New York: The Macmillan Co.

This book cannot be praised too highly; every page is full of sound common sense. The general plan of the book is as follows: in nine chapters the author discusses the home and its surroundings, feeding, sleep and rest, play and growth, child nature and education, steady nerves and healthy mind, care of the child's body, common diseases and disorders of childhood, prevention of contagious diseases and common disorders of childhood, and common emergencies of childhood. The chapters on food, diseases, care of the body and so forth, are thorough, sound, and excellent in every way, but might have been written by any experienced common-sense physician; the chapters on play and growth, child nature, and steady nerves and healthy mind are the best that the reviewer has ever seen in any book, and show a very unusual

insight into child nature. In simple, beautifully chosen language, the author discusses the mental and moral training of children in a truly masterly manner. It is a pleasure to note the entire absence of the words "child psychology" in this book; it is a pleasure to get away from fads and "ologies" of all sorts; it is a relief to find someone who has observed children with true understanding, and who knows how to put his thoughts into such form that they instantly bring to mind practical images. Such a passage as the following is typical of the book:

"Another characteristic of the child nature is what might be called slowness of perception. That this is natural to an untrained mind would seem to be apparent to all, yet, oftentimes fathers and mothers forget this fact, and expect the child mind to comprehend at once, and demand instant obedience. It is not strange that sometimes the young child instinctively prefers to do that with which it is already familiar, or acts slowly in doing something new and unfamiliar. It is something of the same quality inherent in us all—the instinctive desire to understand before we attempt to do. If we are patient and reasonable in our demands, and extend to our children the same courtesy which we ask for ourselves, we shall have much less cause for discipline."

The book is to be thoroughly recommended in every way; it should be read by every parent, and will show them, as the author says, that "the sacred office of parent means more than to be mere providers of physical necessities; it is a teaching office having boundless possibilities."

The Organs of Internal Secretion. By IVO GEIKE COBB, M.D., M.R.C.S. Third Edition. New York: William Wood and Co. 1921.

The author describes this work as a "Book for the General Practitioner," and states that "it makes no claim to be considered an exhaustive or complete account of the endocrine glands, neither can it be considered as a comprehensive therapeutic guide to the administration of the organic extracts."

There is nothing in the text which leads the reviewer to take exception to the latter statement, but its value to the G. P. is open to doubt. What the practitioner needs are facts concerning disease and its treatment, for it is usually a condition and not a theory which confronts him. It would have been better, therefore, if the author had confined himself to a discussion of the few facts that are known, and omitted to mention many theories.

The chapter on exophthalmic goitre, for example, makes no mention of the important evidence afforded by estimating the basal metabolism in this condition, but after mentioning psychoanalysis, water from "goitre wells," hypodermic injection of bile salts, X-ray, "thyroidectin," thymus gland and calcium salts as methods of treatment, he states that operative

interference should be reserved for the grave cases only, and that it should be performed only after all other remedies have failed. After time has been allowed for each of the above remedies to have failed, the results of surgery could hardly be expected to excite enthusiasm for that method of treatment.

The chapters on the other endocrine glands are open to the same criticism; they do not distinguish sufficiently between theory and fact. In the chapter on the Application of the Hormones, it is stated that "The legitimate uses to which thyroid extracts may be put are not confined to myxedema, or even definite sub-myxedema; there are a number of symptoms, sometimes isolated, which may be remedied by this substance." If such isolated symptoms are due to thyroid lack—and here the estimation of basal metabolism will tell the story—the use of thyroid for their relief is legitimate. But the use of thyroid in any given case, because it has "remedied" a similar symptom in another case is unjustifiable, and occasionally dangerous.

The book is clearly written, and understandable. Physically it is attractive, because of its clear print and comfortable size. Because of the lack of definite statements concerning the internal secretions, it is of questionable value to the practicing physician. Granted that few definite statements can as yet be made concerning the endocrines, it were better not to clutter the field with speculation and theory, which lead too often to loose thinking and the indiscriminate use of glandular preparations.

"The Pathological Gall-Bladder." *Annals of Roentgenology*, Vol. II. By ARIEL W. GEORGE, M.D., and RALPH D. LEONARD, M.D.

The subject is presented in the form of a monographic atlas and is designed for a book of reference, particularly for those who are specialists in roentgenology. The captions of the illustrations and the introductory text of each division are printed in English, French and Spanish. It contains one hundred and thirty-five roentgen ray studies, three of which are photographic and two text illustrations, all of which are exceptionally good.

The first chapter is historical. In the second, the authors discuss in detail the technique which they have found most satisfactory, and describe the apparatus necessary for satisfactory work. In the third chapter there is a very good classification of gall-stones, and the differential interpretation of gall-stone shadows from shadows presenting a similar appearance is well covered. The authors attribute considerable diagnostic importance to the presence or absence of the gall-bladder shadow and discuss its differentiation from other shadows which may resemble it.

In the opinion of the reviewer, the appearance of a shadow resembling the gall-bladder in

outline should be given very little weight in the final diagnosis.

Under the heading of "Indirect Evidence," the authors discuss the data obtained from an examination with the barium meal and its value in the diagnosis of gall-bladder disease, and the importance of this evidence is rightly emphasized.

On the whole, the book is a convincing presentation of the value of the X-ray in the diagnosis of gall-bladder disease. It should be remembered that it is written as an atlas and not as a text book.

Radium Therapy. By FRANK EDWARD SIMPSON, A.B., M.D., Professor of Dermatology, Chicago Policlinic, etc. C. V. Mosby Co. 166 original engravings.

With the ever-increasing use of radium by clinicians, many of whom have little idea of the physics and biologic effects of radioactivity, such a book as *Radium Therapy* should prove very useful. It is clear, concise, scientific (as far as is possible in this comparatively unexplored field) and practical.

The author starts, of course, with an outline of the history, chemistry and physics of radioactive substances. He gives in considerable detail the experimental work upon which the practical application of radium is based. He describes the method of obtaining emanation and the various ways of applying radium for therapeutic purposes.

Dosage and the technic of radiation are treated at some length, after which the application of radium therapy in the special branches of medicine is considered.

Although the author is himself a dermatologist, his experience with the use of radium in surgery and in medicine would seem to be sufficiently wide to enable him to speak with a good deal of authority upon the subject.

His book is thorough in its fundamentals, sound in its principles, and represents the best opinions of the present day in regard to radium therapy.

ASTHMA: ITS PATHOLOGY AND TREATMENT.

BROWN (*Edinburgh Med. Jour.*, Feb., 1922) discusses in a practical way, with an elaborate bibliog-

raphy, the subject of the pathology and treatment of asthma. His remarks on the treatment of this condition are practical and sound. The list of references is particularly full, especially concerning the English and German investigators. The references to American writers on this subject are conspicuous by their absence.

[J. B. H.]

OBSCURE INTESTINAL COLIC.

GRAY (*Brit. Med. Jour.*, Feb. 18, 1922) discusses the general subject of obscure pain of abdominal origin, briefly summarizing his opinion as follows:

"Obscure intestinal colic may arise from temporary causes and be of no real significance; its treatment may be medical, or it may constitute a grave warning of an impending surgical crisis.

"A full understanding of its significance depends, I am convinced, on an appreciation of the fact that the bowel itself is insensitive; that colicky pain arises from, and is referred to, the mesentery; and that the mechanism of colic consists in the natural attempt of the bowel to drive onwards a diseased or inert area, thereby inducing an abnormal tension on the associated mesentery."

[J. B. H.]

BLEEDING ULCER OF THE DUODENUM ASSOCIATED WITH CHOLECYSTITIS.

JUDD (*Ann. of Surg.*, April, 1922) calls attention to the existence of certain cases in which bleeding of a more or less severe type, with a probable diagnosis of gastric or duodenal ulcer, has occurred in cases which on operation are found to be associated with a more or less severe degree of cholecystitis. He reports four cases in detail and states that there is abundant evidence to show that cholecystitis and hepatitis may be the source of the infections which results in bleeding, and he also thinks there is evidence which suggests that cholecystitis may be the source of the infection causing this symptom even in the presence of ulcer of the stomach or duodenum.

[E. H. R.]

THE TREATMENT OF SURGICAL TUBERCULOSIS WITH THE CARBON-ARC LAMP.

SAUER (*Ann. of Surg.*, April, 1922) writes that the carbon-arc lamp is an effective agent in curing cases of surgical tuberculosis; that it is as effective as the natural sunlight and has the advantages of convenience and independence of the weather; that it is just as effective, if not more so, than the x-rays, without the attendant dangers; that it is far more effective than the quartz-mercury vapor lamp, as has been amply demonstrated by Roy.

[E. H. R.]

THE CAUSE OF DEATH IN HIGH INTESTINAL OBSTRUCTION.

ELIAS (*Ann. of Surg.*, April, 1922) draws the following conclusions from his observations:

1. That from the intestinal content in cases of high obstruction, a poison can be isolated by precipitation with alcohol, extraction with boiling water and reprecipitation with the aid of magnesium sulphate.

2. That it is not possible to obtain such a poison with this method from the intestinal content of a normal dog prepared immediately after removal.

3. That a poison which, when judged by the means at our disposal, is identical, can be obtained from conditions other than actual obstruction, such as the intravenous injection of the high obstruction

toxin into normal animals, the removal of the adrenals, portal obstruction, and in experimental, acute, fulminating, non-bacterial peritonitis.

4. That this poison is undoubtedly elaborated in the cells of the greater part of the mucosa of the small intestine, but chiefly in those of the duodenum, and that it is manifestly excreted, partly into the lumen of the intestine, but the larger part passes into the lymph stream.

5. That the clinical similarities between acute pancreatitis and high obstruction are due either to a close relationship between the toxins involved, or possibly to the fact that acute pancreatitis actually produces conditions in the intestinal mucosa favorable to the production of the same toxin as is found in cases of high obstruction.

6. Since crepsin fails to exert any action upon the toxin, and since the toxin shows no lymphagogic action whatever, it seems necessary to conclude that the toxin is neither a proteose nor a hereto-proteose.

7. That the clinical advantage of gastric lavage may be explained by the removal of the toxic content and the favoring thereby of an increased excretion into the lumen of the intestine. In addition to this treatment, should be added the introduction of large amounts of saline, both intravenously and by the rectum, to further the excretion of the toxin both by the bowel and by the kidneys.

8. That the finding of the toxin in the intestinal content after the removal of the adrenals suggests that clinically adrenalin should be added to the saline infusion in sufficient amount so that a continuous supply of adrenalin is being furnished.

[E. H. R.]

TREATMENT OF FEBRILE ABORTION.

MAUTHNER (*Wien. Klin. Woch.*, April 6, 1922) discusses the individualized treatment of septic or febrile abortion, dividing cases into two groups, according to whether the cervix is or is not dilated or easily dilatable. For the former class, he recommends digital curettement, followed by irrigation, ergot, pituitrin, and wick drainage; for the latter, in addition, a pre-emptive digital dilation or anterior colpohysterotomy.

TREATMENT OF LISPING.

STERN (*Wien. Klin. Woch.*, April 20, 1920), from Frösche's clinic for speech defects, in Vienna, discusses the treatment of the varieties of lisping.

[R. M. G.]

TREATMENT OF BARTHOLINITIS.

WEITGASSER (*Wien. Klin. Woch.*, April 27, 1922), from Matzenauer's clinic at Graz, reports nine cases of suppurative Bartholinitis treated by simple, conservative methods with successful result.

[R. M. G.]

NOSOGRAPHY IN MODERN MEDICINE.

FABER (*Annals of Medical History*, March, 1922), professor of internal medicine at the University of Copenhagen, Denmark, in an elaborate article on nosography in modern internal medicine, beginning with Sydenham, traces the work of the early English nosologists and the Paris school of anatomic diagnosis, through German physiological medicine and the bacteriological clinic, to present-day functional diagnosis and constitutional pathology. In his final remarks he summarizes the evolution of nosography, and points out that the final aim of medicine is to require such a knowledge concerning the etiology and consequent development of morbid

processes as to enable the adoption of the best and correct methods of action in prevention or treatment. [R. M. G.]

THE DIAGNOSIS AND TREATMENT OF TUBERCULOUS EMPYEMA.

HEDBLOM, C. A. (*Surgery, Gynecology and Obstetrics*, April, 1922), writes:

1. Primary or idiopathic pleurisy with effusion, in a large proportion of cases, is probably tuberculous in nature.

2. A past history of pleurisy with effusion is common in cases of tuberculous empyema. In many cases the effusion is serious at the onset.

3. Tuberculous pleurisy may be primary or it may be secondary to a pulmonary, peritoneal, or other tuberculous lesion.

4. The onset of a tuberculous effusion may be insidious or it may be sudden and associated with an acute and severe constitutional reaction. A mixed pleural infection due to the perforation of a tuberculous cavitation often runs an acute and rapidly fatal course.

5. Diagnosis of tuberculous empyema is made by demonstration of the bacilli in the exudate, by animal inoculation, or by examination of the sectioned pleura.

6. A sterile effusion is probably tuberculous. An infected effusion may be tuberculous.

7. Empyema following primary idiopathic pleurisy with effusion, or empyema of insidious onset, especially in the presence of a pulmonary or other tuberculous condition, is probably tuberculous.

8. Empyema may be tuberculous in spite of persistently negative findings over a long period of time.

9. In a closed pleural cavity a sterile effusion, whether serous or purulent, should not be treated by open drainage, except in the presence of an impending perforation of the chest wall.

10. Repeated aspiration of only part of the fluid present is indicated in cases of serous effusion producing definite dyspnoea on exertion or symptoms of circulatory embarrassment.

11. The replacing of aspirated fluid by nitrogen or filtered air may be indicated in cases in which there are symptoms of active phthisis referable to the same side as the effusion.

12. A sterile purulent effusion should be treated as though it were serous if the lung expands when fluid is withdrawn. If the lung is fixed in a collapsed condition, or if the effusion persistently recurs, an extrapleural plastic operation is indicated.

13. Effusion in a closed cavity showing a mixed infection should be treated by the closed method with antiseptic solution irrigation, or by open drainage; the open drainage is indicated especially in cases of severe infection associated with extensive pulmonary tuberculosis, making irrigation hazardous.

14. Tuberculous empyema with a large bronchial fistula should be drained by the open method.

15. A large tuberculous empyema with mixed infection from a previous drainage operation or from spontaneous perforation of the chest wall requires a plastic operation, preferably with Dakin's solution.

16. A plastic operation, involving closure of a bronchus, offers the only prospect of cure in case of an associated large bronchial fistula.

17. Dakin's solution irrigation may be contraindicated in the presence of an extensively diseased lung, owing to its corroding action on any superficial lesion, possibly resulting in hemorrhage or the formation of a bronchial fistula.

18. A plastic operation is usually eventually required in the case of closed cavities when the empyema is of long standing, and of all large, open, secondarily infected cavities.

19. An extrapleural rib resection is indicated for the collapse of closed sterile cavities. The Boillin-Wilms operation is especially suitable for the collapse of large cavities without excessive thickening of the parietal pleura or rib deformity.

20. A skin or skin muscle plastic is indicated for the obliteration of relatively small cavities. Cases of long standing associated with greatly thickened pleura require an extensive resection of the entire chest wall after the method of Schede.

21. Operation in several stages is especially indicated in the treatment of tuberculous empyema, and, if practicable, it should be preceded by antiseptic solution irrigation. Such treatment should extend the indications for operation and should lower the post-operative mortality. [E. H. R.]

INFECTIOUS JAUNDICE IN BOMBAY.

PARMANAND (*Ind. Med. Gazette*, Feb., 1922) reports seven cases of epidemic jaundice in Bombay, in January, 1922. The symptoms at the beginning were headache, intestinal disturbance, and high, irregular fever. During this febrile period which lasted from four to eight days acute congestion of the bulbar conjunctiva was a well marked feature. Then followed a period of about eight days in which the fever dropped and deep jaundice developed, intestinal disturbance was aggravated, and there was nausea, vomiting and extreme weakness. The pulse became feeble and there was restlessness and a tendency to hemorrhage. After this period a gradual convalescence began. Spirochaetes were recovered from the urine and cultivated, some forms resembling very much the *Treponema pallidum*. Intravenous injections of serum from convalescent patients and from actively immunized horses are recommended. Salvarsan has also proved useful. [L. D. C.]

GROWTH PROBLEMS FOLLOWING OSTEOMYELITIS OF ADOLESCENT LONG BONES.

SPEED, K. (*Surgery, Gynecology and Obstetrics*, April, 1922), from a study of a considerable number of cases, states that one should be extremely conservative in draining acute suppurative epiphysitis of adolescent long bones, and always in operating one should not reflect the periosteum any more than is necessary, that injury to the blood supply of the epiphysis is most serious, and he makes the following statements in conclusion:

1. Remember the law of nutrient arteries in relation to growing long bones, i.e., the nutrient arteries are directed toward the elbow and from the knee, and the epiphysis toward which the artery is directed unites first. The tibia is an exception, of course. Consequently, the lower epiphysis of the femur, the upper epiphysis of the tibia, the lower epiphysis of the radius and ulna, and the upper epiphysis of the humerus all unite at last in their respective bones, and must be the most guarded.

2. Unless a bowing deformity in the leg or forearm tends to manifest itself rapidly and to cause great loss of function or threaten skin necrosis, splint correction of the extremity for at least one year is favored.

3. If both clinical and x-ray examination during the course of the year show that the bone is arrested in growth, a shaft resection of the companion bone, remote from the epiphysis, is performed to equalize length. Simple means (kangaroo tendon) of holding the resected ends in apposition are used, followed by a firm splint until union takes place.

4. If the child is young (many years and inches of growth expected), after two or three years, when it is quite positively established that the epiphysis of the damaged bone has ceased all growth and is

obliterated, the analogous epiphysis of the fellow bone may be excised (epiphysectomy) to stop its overgrowth. Each bone then grows at an equal rate from the remaining epiphysis, and there is no fear of subsequently appearing bowing deformity. Length deformity will persist. [E. H. R.]

AN ANALYSIS OF THE END-RESULTS IN TWO HUNDRED THIRTY-TWO HYSTEROMYOMECTOMIES, WITH SPECIAL REFERENCE TO OVARIAN CONSERVATION.

CLARK, J. G., and NORRIS, C. C. (*Surgery, Gynecology and Obstetrics*, April, 1922), write as follows:

1. Hysteromyomectomy is productive of excellent end-results whether or not ovarian conservation is practised. Of all patients in our series, over 99.5 per cent. were cured or improved, and over 83 per cent. declared that their general health was good or improved one year or more after operation.

2. Better end-results and greater comfort to the patient can be secured as the result of ovarian conservation.

3. Everything being equal, better end-results follow the conservation of both ovaries than the retention of one, but one ovary is far better than none.

4. Conserved ovaries seldom give subsequent trouble. Among 171 cases in which ovarian conservation was practised, 261 ovaries were conserved, and in none of these patients was a second operation for the removal of the ovary necessary. This is a strong argument in favor of ovarian conservation in this class of cases, for if the conserved ovary does not give trouble, there can be no excuse for its removal.

5. That conserved ovaries may give subsequent trouble is conceded, as is also the fact that the series of cases quoted may have been unusually fortunate in this respect. Successful ovarian conservation depends upon the condition of the ovary at the time of operation, the maintenance of an adequate blood supply, and the retention of the ovary in its normal position.

6. We believe that undue emphasis has been placed upon the frequency of cystic and other forms of degeneration in conserved ovaries, and that attention to the points just mentioned will largely abrogate such disturbances.

7. Bearing in mind the fact that good results can be secured by performing bilateral oophorectomy, it is often better to sacrifice a doubtful ovary than to spare it. This is a point, however, on which each case must be judged individually.

8. When both ovaries are removed, the surgical menopause is by no means severe in all cases, those patients who suffer unduly being in the minority.

9. The age of the patient is not an unfailing criterion as to the severity of the surgical menopause in any given case. Young women will sometimes bear the loss of both ovaries well, whereas some of the most severe phenomena of the surgical menopause encountered in this series have occurred in patients past 40 years of age. This does not imply that the age is an unimportant factor in considering the question of ovarian conservation. Other things being equal, there is no doubt but that younger women suffer more severely as a result of a bilateral oophorectomy than do those who are older.

10. A more important guide than the age, however, is the temperament of the individual patient. The highly strung, neurotic woman is likely to suffer more severely than her more phlegmatic, asexual sister.

11. Each case should be individualized. The temperament of the patient should be studied, and a correlation of this with the history and the pathological process found at operation should determine the type of operation to be performed.

12. Conserved ovaries functionate.

13. Keep in those patients in whom the ovary

does not function permanently, the occurrence of the surgical menopause is less abrupt and severe than in those women upon whom a bilateral oophorectomy has been performed. Among the former class of cases the artificial menopause generally resembles the normal menopause more closely than does that following the removal of both ovaries. [E. H. R.]

HUMAN ACTINOMYCOSIS, WITH SPECIAL REFERENCE TO SOURCE AND MODE OF INFECTION.

MATSON, W. W. (*Surgery, Gynecology and Obstetrics*, April, 1922) writes as follows:

1. There is but one true species of micro-organism capable of producing actinomycosis in man and lower animals, and this is the one isolated by Wolff and Israel and later more fully described by Wright.

2. There is no convincing clinical evidence supporting the theory that this organism is a normal inhabitant of the oral cavity and gastro-intestinal tract of man.

3. There is much clinical and biological evidence that his micro-organism has its source outside of the human body and is capable of a dual existence; first, as a saprophyte in old soil from which it gains access to grains and grasses, and through this medium or intermediary host, so to speak, it becomes capable of infecting man and lower animals.

4. In order for infection to take place, two things are necessary; first, an abrasion of the tissues; second, the fungus must in some way be brought directly in contact with this abrasion.

5. Animal-to-man infection is far more common than we have been led to believe it was by earlier investigators.

6. Human actinomycosis is not a rare disease, but a disease which is often overlooked or incorrectly diagnosed.

7. Every inflammatory swelling of chronic or sub-acute nature with persistent and recurring sinus formation should be carefully investigated for this disease.

8. A negative smear, on first examination, does not rule out infection, as the fungus, in the presence of mixed infection, is often very difficult to find.

9. The disease should always be kept in mind in every case of atypical pulmonary tuberculosis and should be looked for in cases suffering with chronic purulent bronchitis or bronchiectasis.

10. Early treatment of superficial lesions are highly successful. Internal infections are extremely fatal and hopeless. [E. H. R.]

THE MANAGEMENT OF ACUTE CRANIAL INJURIES BY THE EARLY, EXACT DETERMINATION OF INTRACRANIAL PRESSURE, AND ITS RELIEF BY LUMBAR DRAINAGE.

JACKSON, HARRY (*Surgery, Gynecology and Obstetrics*, April, 1922), writes as follows:

1. In most acute injuries of the brain, the cerebrospinal fluid pressure is a fair index as to the severity of the lesion. Dependable prognosis can be made by any increase or decrease of this pressure.

2. A new clinical classification of injuries of the brain based upon cerebrospinal fluid pressure alone, as shown by the mercury manometer, is superior to the accepted classification of concussion, contusion, and compression.

3. The pathogenesis of acute injuries of the brain demonstrates that the principal effect of the oedema of the brain and haemorrhage is to interfere with the absorption of cerebrospinal fluid by the usual paths; this sets up a vicious circle, causing further pressure on the brain by the accumulating fluid in the basal cisterns below the tentorium cerebelli, and in the lateral ventricles, which presses the brain upward against the dura and produces cortical anaemia. The cortical anaemia, if unrelieved, quickly leads to gliosis, causing lasting changes in

the character, disposition, and mentality of the patient, if he recovers from the brain injury.

4. The relief of the increased pressure on the brain and the re-establishment of the normal path of absorption of the cerebrospinal fluid can be obtained by repeated lumbar drainage—which in acute injury cases is absolutely without danger.

5. Lumbar drainage is superior to sub-temporal decompression in relieving pressure below the tentorium cerebelli, and has the further advantage that it leaves no mutilating skull defect. The use of concentrated salt solutions intravenously lowers cerebrospinal tension but does not remove blood.

[E. H. R.]

ANOMALOUS ABDOMINAL MEMBRANES.

TAYLOR, ALFRED S. (*Annals of Surgery*, May, 1922), presents a 60-page article on this subject, representing his experience with 49 cases. The article is concise and well presented. The following summary is appended:

1. Anomalous membranes are present in from 15 to 20 per cent. of new-born infants.

2. They result from atypical peritoneal fusion during fetal life. Many of them are probably modified by later pathological changes due to continued traction, irritation, or low-grade inflammation.

3. They occur in the hepato-duodenal region, at the duodeno-jejunal angle, and about the caecum, ascending colon, hepatic flexure and beginning transverse colon.

4. Two or more of these regions are involved in the majority of individual cases. Groups of cases illustrating the results of treatment of the membranes found in the individual locations have been published by various men. Hepato-duodenal group by *Harris*; duodeno-jejunal groups by *Kellgren*; and pericolic group (Jackson's membrane) by *Jackson*, but sufficient emphasis seems not to have been put upon the fact that two or more of these lesions exist in the majority of individuals who fall within the large group.

5. They cause mechanical disturbances, fixation, angulation, compression and torsion of the digestive tract, resulting in partial, continuous and often increasing obstruction. This, in turn, frequently causes distention proximal to the obstruction.

6. Symptoms result when the obstruction becomes greater than the peristaltic efficiency can easily overcome. This balance may be gradually lost over a long period of time, with resulting slowly increasing symptomatology. It may be suddenly lost as the result of a prostrating injury or illness, the obstruction remaining constant while the viscera, becoming atonic, is no longer competent to overcome it. Sometimes the viscera regains its relative power and the symptoms improve. Often the viscera can never overcome the handicap and symptoms are continuous and progressive.

7. For a long time it was thought that these cases developed symptomatology only after twenty years or more of age. The investigations of *Kerten* in infants and children suffering from malnutrition, cyclic vomiting, recurrent acidosis, etc., show that abdominal examination and studies of the barium gastro-intestinal series give precisely the same findings as do the older cases in which operation has demonstrated the lesions, and caused cure in a high percentage of cases. This would indicate that symptoms appear in definite form at any period of life when the balance of peristaltic efficiency against the partial obstruction is lost.

8. The symptomatology consists of digestive disturbances previously described; general nutritional

disturbances; nervous debility, usually termed neurasthenia (and occasional mild psychosis). At some period the appendix is likely to become tender to pressure, is assumed to cause the symptomatology by "reflex action," whatever that may be, and is removed, with failure to cause improvement.

9. There are usually tender spots in the mid-epigastrium, over the appendix, over caecum and ascending colon, and over the duodeno-jejunal angle, depending upon the presence of the various lesions. There is varying dilation and ptosis of the stomach, and varying dilation of caecum and ascending colon. In marked obstruction at the duodeno-jejunal angle, the dilated duodenum can be made out.

10. Examination of gastric contents and stools gives no evidence of value, as a rule.

11. The most important element of evidence is found in the barium gastro-intestinal series. It must be a good series, with sufficiently frequent plates. The plates must be read by one experienced in these cases. It is common to receive typewritten reports that the plates are "negative," or that the digestive tract is "normal," when inspection of the plates shows characteristic evidence to be on the plates. Fluoroscopy should be done by one experienced in these cases, especially to determine the presence of obstruction at the duodeno-jejunal angle, indicated by marked distention of dependent duodenum with writhing and rushing of the contents back and forth. The pictures are not quite so conclusive, and on the operating table the duodenum may be empty and the condition not so obvious.

The plates are likely to show:

Hepato-duodenal Membrane: The stomach dilated, posed, with varying peristaltic activity. With or without retention. The apex of duodenum fixed high, sharply angulated and showing little mobility. The cap is often deformed but not in the way characteristic of ulcer. The second part of duodenum is likely to be compressed and narrowed.

Duodeno-jejunal Angle Obstruction: Dependent duodenum, if dilated, may or may not show definitely on the plates.

Pericolic Membrane: The hepatic flexure shows high fixation (often near the duodenal apex), angulation, and often transverse colon descends in contact with ascending colon. Caecum and ascending colon are dilated, ascending colon often showing constriction at about its middle. Appendix, if still present, usually retains the barium for long periods. Ileocaecal valve is often incompetent.

12. Treatment: (a) Prolonged medical. (b) Surgical. Best incision is "transverse right rectus," as it gives best exposure of the whole field, and post-operative adhesions are in least troublesome situation. (c) Post-operative. Abdominal massage. Medical supervision of diet and general hygiene, etc.

[E. H. R.]

ACUTE HEMATOGENOUS OSTEOMYELITIS.

STARR, C. L. (*Archives of Surgery*, May, 1922), differentiates between acute hematogenous osteomyelitis and the sub-acute and chronic form. He is in the habit of employing two or three drill holes into the bone instead of chiseling definitely through the cortex into the medulla. In many cases this is sufficient to produce ample drainage. In no case does he purposely open the medullary canal at first, and he believes that the old treatment of previously opening in the medullary canal for two or three inches up the shaft is, in the light of his experience, a pernicious one. The article is a distinct contribution.

[E. H. R.]

EPITHELIOMA OF THE GENITO-URINARY ORGANS.

BRODERS, A. C. (*Annals of Surgery*, May, 1922), taking information from 173 cases representing 23.65 per cent. of 2000 cases of general epithelioma observed in the Mayo clinic from May 1, 1904, to July 24, 1915, furnishes a statistical report upon the incidence of this condition in the various parts of the genito-urinary tract. He gives 24 pages of tabulated and charted results. [E. H. R.]

THE PRESENT STATE OF OPERATIVE OBSTETRICS REFERRING TO THE ABUSE OF CAESAREAN SECTION.

POLAK, J. O., and BECK, A. C. (*Surgery, Gynecology and Obstetrics*, May, 1922), state that surgical intervention is being too freely employed to terminate labor, and furthermore that the results for mother and child from such interference (oftentimes unindicated) with the physiological processes of labor do not justify their employment.

That the adoption of the principle and practice of aseptic intelligent expectancy in labor, when the factors of labor are known to be normal, or approximate the normal, is still the safest method of delivery, not only for the mother, but for the foetus.

That there is a high morbidity even in the clean caesarean section, very much higher, in fact, than is common in operations for pelvic tumors, such as fibromyomata and ovarian cysts. This is due to the presence of infective bacteria in the cavity of the puerperal uterus, which migrate from the vagina to the interior of the uterus, through the open cervix.

That even in expert hands there is a definite maternal risk from caesarean section, greater than is generally known. Our mortality studies show that this ranges from 2.9 per cent. to 14 per cent., depending on the time in labor at which operation is done, after rupture of the membranes and on the amount of vaginal invasion present.

And finally, in view of these facts, we feel that every pregnant woman should have greater prenatal study and care than is commonly given her, so that complicating conditions may be recognized, prevented, or corrected, before labor, and where this is not possible, the knowledge gained from this study will permit the obstetrician to conduct the labor in such an intelligent and aseptic manner, as to minimize the dangers from abdominal delivery. [E. H. R.]

HYPEREMISES GRAVIDARUM.

PADDOCK, C. E. (*Surgery, Gynecology and Obstetrics*, May, 1922), has recently treated several cases of the pernicious vomiting of pregnancy by use of the duodenal tube, thus resting the stomach, and giving the patient nourishment during this critical period. He suggests that this may be a means of saving a certain number of desperate cases, and can easily be used in place of jejunostomy, which has been resorted to by several surgeons recently in the more desperate type of case. The report is a suggestive and valuable one. [E. H. R.]

CONGENITAL MEGACOLON IN ADULT.

FOWLER, W. F., DAVIDSON, S. C., and MELLON, R. R. (*Surgery, Gynecology and Obstetrics*, May, 1922), write as follows:

1. The so-called idiopathic megacolon is relatively infrequent in childhood and rare in the adult.
2. The only congenital feature of megacolon is the redundant sigmoid.
3. The unobstructed redundant sigmoid may be nearly or quite symptomless.
4. The degree of obstruction, from whatsoever cause, determines the subsequent course. a. Relatively slight obstruction (the "angulation" of Delaunoy) produces a definite syndrome without dilatation or hypertrophy. b. Acute obstruction usually vol-

untains, either primary or superimposed upon hypertrophy, induces sudden dilatation and the desperate picture common to such obstructions. c. Chronic obstruction causes gradual dilatation and compensatory hypertrophy, the type described by Hirschsprung.

5. Kinking, or valve-like action at the rectosigmoid junction is the usual cause of obstruction. When the rectum, also, is involved, anal spasm is a likely factor.

6. The surgical treatment of megacolon aims at removal of the crippled bowel and restoration of the intestinal continuity. [E. H. R.]

DIAGNOSIS OF PULMONARY CONDITIONS IN CHILDREN.

PIRSON, JOHN W. (*Am. Jour. of Ro.*, Jan., 1922), seeks to discuss certain types of pulmonary conditions in children. The writer finds that it is almost impossible to set a standard for diagnosis in cases of pulmonary infections because of the varying results of tests applied. For example, a case will be found pathologically by x-ray examination, where nothing abnormal is observed on physical examination. Then, too, it is difficult because there are numerous factors causing changes in the lungs which do not have any direct bearing on the case.

In treating the numerous types of pulmonary conditions, the writer observes:

Acute infections: Acute bronchitis causes no changes which are demonstrable by means of x-ray examination.

Bronchopneumonia: Bronchopneumonia in its acute stage is characterized by areas of consolidation; passing to the chronic stage these areas clear, but there is a very extensive fibroid infiltration outlining the bronchial tree with thickened and dilated bronchi.

Tuberculosis: Children developing a very early tuberculosis usually die. In these cases it was noted that no changes were shown before the 6th month. In older children the enlargement of the mediastinal glands give almost positive evidence of tuberculosis.

Thymus: Cases of persistent thymus, diagnosed as such because the patients were too young to have tuberculous glands, showed marked improvement under x-ray treatment.

Rickets: Pulmonary findings in rickets usually occur within the first three years of the child's life. It is difficult to diagnose any concurrent lung infection in such cases, owing to the various conflicting changes occurring throughout the entire chest. [H. A. O.]

ROENTGENOTHERAPY OF THE THYROID.

TYLER, A. F. (*Am. Jour. of Ro.*, Jan., 1922, Vol. ix), discusses only cases of hyperthyroidism; all other types of goiter should be treated by surgical or medical means, rather than roentgenotherapy.

The three types of hyperthyroid cases, i.e., the toxic adenoma, the hyperplastic toxic goiter, and the exophthalmic goiter, respond to roentgenotherapy in the order named.

In treating patients suffering from thyroid disease, the following schedule is adopted: First, a detailed history is taken, both family and personal. Then a thorough physical examination is made, followed by an x-ray examination of all teeth and accessory sinuses and a thoroscopic examination of the chest, together with plates in oblique position. After this a basal metabolic estimation is made; then x-ray or radium is employed, radium being used only in cases requiring hospitalization. Ambulatory patients are treated by x-ray, using 104 inch spark gap, 6 mm. of aluminum and one thickness of sole leather, 8 inch anode skin distance, 6 ma. of current for 15 minutes over each area, treating three areas, one over each lobe and one over the thymus region. This dosage administered three times, four weeks elaps-

ing between each treatment, is usually all the patient needs.

The advantages of roentgenotherapy for toxic goiter over other treatments are:

1. There is no surgical shock, hence the mortality is very low.
2. It is successful where surgery fails.
3. It can be employed in inoperable cases.

[H. A. O.]

A REVIEW AND CLASSIFICATION OF BONE SARCOMAS.

EWING, JAMES (*Archives of Surgery*, May, 1922), presents a most thorough and learned treatise upon this still obscure subject. He describes the various varieties according to his own classification, which is included in the text. The text is well illustrated by photographs and microphotographs and the following general conclusions are reached:

1. It has been shown by physical computation, histologic changes in the tumor tissues, and clinical results, that it is possible to deliver an effective dosage of roentgen ray or radium to all parts of many osteogenic sarcomas where the tumors are accessible from all sides.

2. The histologic changes demonstrate a slowing of the rate of growth of the tumor cells, by which they are induced to lay down calcific material, or dense hyaline stroma, or bone. With vascular and cellular tumors, hemorrhage and necrosis may be produced.

3. Cellular tumors without much intercellular stroma may undergo complete resolution and disappear.

4. Tumors producing much intercellular material can probably not be made to disappear by present technique with physical agents. The most that can be hoped for such tumors is the sclerosis or ossification of the tumor tissue with cessation of growth.

5. The majority of true osteogenic sarcomas under radiation, while suffering retardation of growth, prove fatal from the usual metastases. It may be said that they would do so under any circumstances; but the possibility that prompt amputation might save some patients may be considered by many as a bar to conservative treatment. On the other hand, the long survival of certain cases heavily radiated and later coming to amputation strongly suggests that effective radiation distinctly postpones metastases.

6. The technique of employing roentgen ray and radium in osteogenic sarcoma can be made much more efficient by the proper selection of cases, by more careful study of the exact anatomic condition to be dealt with, adapting the agents to the conditions as found, and by a judicious combination with surgery.

It is obvious that the problems here involved are of a major character and demand the most intelligent cooperation of surgeon, radiologist and pathologist. From results already obtained, I am convinced that large rewards await the resourceful worker, by using all the means now at his disposal, in reducing the mortality from this lethal disease.

[E. H. R.]

FRACTURE-DISLOCATION OF THE SPINE TREATED BY FUSION.

HIBBS, R. A. (*Archives of Surgery*, May, 1922), presents an article well illustrated with x-ray plates of this condition and makes the following statements in conclusion:

It is evident from the study of these cases that:

1. Many fracture-dislocations of the spine are not recognized.

2. They occur with greatest frequency in the lumbar spine; and the fifth lumbar vertebra is the one most often injured.

3. Those which take place in childhood may not cause symptoms until adult life, when the completed ossification of the vertebrae destroys their capacity for accommodation to altered shape and position.

4. The symptoms are caused by the mobility of these altered joints and ununited fractures. Elimination of motion is essential to complete and permanent relief.

5. Fusion of the articulating bones is a means to that end. It has been accomplished by the operation herein described, with complete relief in every case.

[E. H. R.]

CARCINOMA OF THE LUNG.

BARRON, M. (*Archives of Surgery*, May, 1922), reports on thirteen cases studied at necropsy in relation to its incidence, pathology, and relative importance, and he makes the following remarks in conclusion:

1. Carcinoma of the lung is a rare disease; but its rarity is exaggerated by the failure to recognize many of those cases that do occur. It is only at necropsy that many are revealed.

2. Carcinoma of the lung may be diagnosed clinically. However, a diagnosis is possible only when careful and detailed histories are taken and accurate physical examinations are made. Laboratory and roentgenologic studies may also be helpful. All facts obtained must be carefully correlated. Statistics show that complete examination of the patients have, in the hands of certain practitioners, resulted in correct clinical diagnosis in from 80 to 95 per cent. of the cases.

3. This disease is apparently increasing in frequency, especially during the past few years. Chronic inflammations, such as tuberculosis, are possible factors in the etiology of the disease. The last great influenza epidemic is perhaps another factor. The average incidence has been about two per 1000 necropsies. In our series, during the past few years the increase has been about fourfold. The disease has formed about two per cent. of the cases of cancer encountered at the postmortem studies.

4. Most pulmonary carcinomas develop from the bronchial epithelium. Some originate from the bronchial mucous glands, and only a few arise from the alveolar epithelial cells.

5. Epithelial metaplasia is relatively common in bronchial mucous membranes. This may explain the origin of the comparatively large number of squamous-cell carcinomas in this region.

6. Metastases are common in this disease, and often are numerous. The frequency of metastases to the brain, suprarenals and thyroid is very striking.

7. Pain in the chest, cough and dyspnea occur early. Bloody sputum and asymmetry of the chest are important findings in these cases. Laboratory procedures and roentgenologic studies have thus far not proved of very great assistance in the differential diagnosis.

8. Bronchiectasis is an important complication, especially since it may give misleading physical and roentgenologic findings during the course of the disease.

9. The study of the thirteen cases reported in this paper shows the importance of assuming a new attitude toward this disease with reference to its prevalence and diagnosability. The two cases encountered at the University Hospital during the past year were both recognized clinically; but ten of the remaining eleven of this series were not diagnosed correctly. This fact points strongly to the necessity of greater familiarity with the signs, symptoms and pathology of the disease. [E. H. R.]

THE BOSTON Medical and Surgical Journal

Established in 1828

Published by The Massachusetts Medical Society under the jurisdiction of the following committee:

For three years WILLIAM H. ROBEY, JR., M.D.
ROGER I. LEE, M.D.
ROBERT B. OSGOOD, M.D.
For two years JAMES S. SPOON, M.D.
HORACE D. ARNOLD, M.D.
CHANNING FROTHINGHAM, M.D.
For one year HOMER GAGE, M.D., Chairman.

SUBSCRIPTION TERMS: \$6.00 per year in advance, postage paid for the United States, \$7.50 per year for all foreign countries belonging to the Postal Union.

Material for early publication should be received not later than noon on Saturday. Orders for reprints must be sent to the printer with galley proof of paper. Upon written request, authors will be furnished free one hundred eight-page reprints, without covers, or the equivalent in pages in articles of greater length.

The Journal does not hold itself responsible for statements made by any contributor.

Communications should be addressed to The Boston Medical and Surgical Journal, 126 Massachusetts Ave., Boston, Mass.

HOT WEATHER DANGER TO INFANTS.

WITH the exception of the first two years of life, the summer is the season of lowest mortality and a minimum of disease; but for the infant these months offer the greatest risk and a mortality far higher than at any other time of the year, due entirely to the incidence of acute gastro-intestinal disease. The "Mortality Statistics" of the United States Government show the general tendency for the total death rate in the summer months to be about half that in winter, while the infant diarrheal deaths in August reach three or four times the winter level.

Many of the factors which determine the high summer infant mortality are known, and a further study of mortality statistics shows that the application of our knowledge regarding these factors during the past two decades has resulted in the saving of many infant lives. In 1900 the figures for the total registration area of the United States show an August mortality more than thirteen times that of January. In 1910 this difference had fallen to about nine times, in 1915 well below six times, and in 1920 to about three and one-half times. This last difference is merely an indication of the possibilities still before us. From these figures it is evident that summer diarrhea is to a large degree preventable, and as the agencies carrying

out these preventive measures gradually increase their scope and influence, we look confidently toward an increasing reduction in the mortality and morbidity figures during the months of excessive heat.

Preventive medicine is taking a place of increasing importance in the activities of the general practitioner, and in no sphere can this activity be fostered to greater advantage during the months immediately before us than in the prevention of disease in infants. It is with these considerations in mind that we are reviewing the factors which are well known to play a part in the production of our high infant mortality, hoping that greater interest may be aroused in and further attention paid to these apparently minor considerations, when the possibilities within our reach by so doing are fully appreciated.

The factor longest recognized and having received the greatest attention in the past, is that of proper milk supply. The artificially fed infant has always been the one to suffer most; not primarily because of the inherent difference in the constitution of cow milk as opposed to human milk, but because of the difficulties attendant upon procuring a clean milk (i.e., milk of low bacterial count) during the hot weather. Very great progress has been made in this country along this line, and much of the reduction in our mortality is due to this one factor alone. This, however, has probably made us too confident about our milk supply, and allowed us to overlook possible opportunities for the development of a dangerous degree of bacterial growth in even the best grades of cow milk. How often do we inquire regarding the length of time the milk stands at the back door on warm summer mornings before it is taken in, made up into the formula and placed on the ice? Proper methods of collection, storage, and delivery, can do a great deal toward providing a suitable infant food, but all of these together can not insure against the occasional administration of unsuitable milk. We, therefore, strongly advocate boiling all formulas made for infant consumption during the hot weather, even though the best milk is procurable and all other precautions can be taken. The milk supply is the greatest source of danger, but the importance of avoiding infection from other sources should be mentioned in passing. It should not be forgotten that anything that enters the infant's mouth is a possible carrier of infection.

In recent years, however, additional causes have been found to have a bearing upon the incidence of gastro-intestinal disturbances in hot weather. The infant's capacity for heat regulation, that is, the adjustment between heat production and heat loss has been shown to be important. The two factors known to influence heat production are muscular activity and food intake. The first of these factors is not under

our control in the case of infants, and no attempt should be made to limit muscular activity; but we can regulate food intake, and it is a safe precaution to lower the caloric value of the food given on the very hot days. This reduction may best be made in the artificially fed infant by the substitution of water for part of the milk in the formula, and in the breast-fed by giving a little boiled water before nursings, for the water requirements are greatly increased, water being the vehicle of heat elimination.

McClure and Sauer have studied the question of heat elimination and have shown the important influence which clothing has upon conduction, radiation, and evaporation at the various temperatures. Sauer also has shown how nearly the indoor costume of the average infant in summer approximates that in winter. They advocate the use of less and more permeable clothing, and more frequent baths as means of facilitating heat loss. The possibilities of preventing gastro-intestinal upsets by careful attention to such details becomes more evident when we consider the observations of Helmholz, that infants can tolerate temperatures decidedly above those usually considered harmful without showing any bad effects. He concludes that "it is a matter of improper adjustment of the individual to its surrounding temperature, rather than the height of temperature, that helps to swell the total gastro-intestinal deaths during the summer." The height of the temperature is usually not under our control, but we can materially assist in making a proper adjustment to existing conditions possible.

Exposure of an infant to too intense and prolonged sunlight is also a possible means of upsetting the heat regulating mechanism. In giving infants sun baths, judgment must be shown on the very hot days as to length of exposure and the conditions under which it is made, but we believe that the tendency is to provide far too little, rather than too much sunlight, most infants getting through the summer without even acquiring a healthy tan. Stripping an infant for a sun bath and placing him where there is a moderate circulation of air, will so facilitate heat loss that the temperature will not be raised by a moderately hot sun. On the other hand, this heliotherapy is being valued more and more as a prophylactic and therapeutic agent for a variety of conditions common in infancy. It has long been used in the treatment of bone and joint tuberculosis. More recently, however, its intensive utilization in cases of bronchial gland and lung tuberculosis has very materially altered the prognosis which we now give when such early infections are encountered. The non-tuberculous infections of these parts are also benefited by such treatment. Recently Hess and his co-workers have shown that sunlight alone can have a curative effect upon rickets in infants. They have also

demonstrated, as did Powers and Park and their co-workers, that proper exposure to the sun's rays will prevent the development of rickets in rats even on a very poor diet. Rickets is a very widespread and serious disease in this part of the country, and yet it is largely preventable. Proper education of mothers as to the value of the sun's rays will go a long way in reducing its incidence. As a therapeutic agent in the treatment of certain skin conditions common in infancy, sunlight is also of known value; and the stimulus which it affords to the sluggish appetite is often surprising. The underlying factor in all these conditions is not well understood, but the effect in all is probably dependent upon a stimulation of general metabolism.

Miscellany.

THE GORGAS MEMORIAL.

At the last annual meeting of the Massachusetts Medical Society, Dr. F. B. Lund spoke of the life, character and achievements of General Gorgas, saying in part:

"Out of gratitude for his work in the Republic of Panama, the President of the Republic, Bellisario Porras, has brought it about that the Republic of Panama has appropriated money and land to build in the City of Panama, at the cross-roads of the world, a building to be called 'The Gorgas Memorial Institute of Tropical and Preventive Medicine.' In that building the great work to which General Gorgas devoted his life and the resources of the United States Army, to study and prevent and cure tropical diseases, is to be carried on. The location of the Institute in Panama is ideal, and it will serve as a base from which expeditions will be sent out. Then there is a large hospital close by, the Santo Tomas Hospital, the clinical facilities of which will be at the disposal of the Institute. It is to be an international affair, and the director of this Institute is our own Dr. Strong, whose work in sanitation in all parts of the world has made us so proud of him. This Institute is going to afford a tremendous opportunity for post-graduate study in tropical diseases and will be available to students from our own Harvard Medical School, as well as to students of all other medical schools in this

country. It is going to require an endowment of six million dollars, and there is going to be a campaign to raise this fund as an endowment, not only from the people of America, but from the people of South American countries, and I don't know whether it will be taken up in Europe or not. This money is going to be spent in a way where it will do more good than can be imagined. It is an unselfish project and its scope is international; the doctors should give all they can, but the whole burden should not be placed on the medical profession, but on the public as well. Physicians should be made acquainted with this great humanitarian enterprise, the biggest conception of its kind that I know of."

Dr. R. P. Strong followed Dr. Lund, saying, in part: "It has been suggested that I supplement Dr. Lund's remarks. This Institute, as Dr. Lund intimated, was regularly incorporated under the laws of Delaware last October; and this action was taken following the formal knowledge of the order of the Government of Panama, made through its President, Dr. Poras, to provide a suitable site and a proper memorial building in Panama. Dr. Poras was a devoted friend and admirer of General Gorgas and he felt that this recognition of General Gorgas' services was particularly appropriate. I have just returned from my fourth visit to the Canal Zone, and I have come back impressed more than ever before with the fact that the Canal and the Canal Zone, as they stand today, constitute one of the greatest monuments to sanitation ever created anywhere in the world. The canal really constitutes a wonderful epochal landmark in the history of human progress. General Gorgas was a man who during his lifetime was famous for his achievements in sanitation and science, and he did more to show the world the importance of medical knowledge in relation to human progress than anyone else. It was particularly due to his labors in Panama and Cuba and South America that American sanitation is today known and its value recognized throughout the civilized world.

"Now, a word about the scope of the organization. It has been decided to establish first divisions of bacteriology, pathology, protozoology, helminthology, biochemistry, entomology, plant pathology and animal diseases; and these departments will be organized with laboratories for research work, particularly in connection with the study of the mode of spread of the most important infectious diseases of man and animals. There will be close coöperation between the Institute and the Ancon Hospital and the Leprosarium. In addition to the above subjects, which are regarded as fundamental components of the work of the Institute, tropical botany and the biological effect of sunlight will also receive attention. Particular attention will also be paid to the study of economic problems in connection with the control of animal

and plant diseases. Provision will also be made for the instruction of a limited number of students. The courses of instruction will be designed especially for those who have had laboratory training before. A limited number of qualified research workers will also be received. The privileges of the Institute will be extended and an opportunity made to attract investigators from scientific institutions in different parts of the world to carry on research work, both in the Institute and by expeditions into the neighboring republics of the tropics.

"To summarize briefly—The President of one of the smaller South American republics, a country whose finances are already overtaxed, has made an offer to provide a memorial to an American, to erect a memorial institute or monument which will really be one to American medicine and American sanitation. Now does it not become the duty of the American people to provide a suitable endowment fund with which to carry on the work of this Institute? It seems to me that it is the duty of every one of us to bring about the realization of this project as soon as possible, and, as Dr. Lund said, the burden should not be borne by the medical profession alone, the contributions should be made by the American people, but I think the doctors of Massachusetts, when asked by laymen, should be able to tell the facts about this great enterprise."

BUSINESS PRINCIPLES APPLIED TO THE MANAGEMENT OF WELFARE AGENCIES BRING INCREASED RETURNS.

The application of modern business principles to welfare agencies, and the increased returns on the funds contributed effected thereby, are described in a report just made public by the U. S. Department of Labor through the Children's Bureau. This report, entitled "Office Administration for Organizations Supervising the Health of Mothers, Infants, and Children of Preschool Age," is the outgrowth of requests for advice which came to the Children's Bureau from organizations in various cities. It embodies the experience of members of the staff whose services were loaned for studies and consultations, and the results of a study of methods used by 200 nursing agencies in both large and small communities. Although the report is directed especially toward the needs of agencies supervising the health of mothers and young children, certain fundamental principles set forth are applicable to the conduct of any office in the social field.

The immediate results of the reorganization of the first agency studied, which affected both the nursing staff and the office force, were: (1) a marked increase in the nurses' time available for field work, due to elimination of duplicate clerical work on their part, and to increased office clerical assistance. (2) An increase of of-

office output, due to redistribution of duties and orderly rerouting of clerical work. (3) Increased accuracy in handling records and office detail. (4) Elimination of lost motion, with its waste of time, energy, and space, accomplished by standardizing routing duties and rearranging the office equipment. In addition to these immediate results the new system laid the foundation for orderly development and future economical administration of the association's affairs.

"It is indisputable," the report states, "that in the long run modern office management enables a society to do more work and better work than was possible at the same cost in old ways." If high standards of nursing service are to be maintained, strict requirements regarding the education, training, experience, and character of the nurse must be compensated by adequate professional salaries. The skilled nursing staff, moreover, must be supported by a skilled office force, intelligently and adequately equipped and directed.

The report is not intended for the larger organizations alone. It is not unreasonable to suppose, it states, that the waste occurring in the small public health nursing organizations throughout the nation bulks greater than the total waste of the large organizations. The office may be the desk of the one nurse who is executive and staff at one and the same time, but the application of the fundamental principles of management are nevertheless necessary to efficient service.

The report is written with full knowledge of the financial limitations which hamper many struggling societies. "The nonpaying business concern goes out of existence while the public health nursing organization usually struggles on through many lean years doing countless things plainly undesirable from the mere inability to meet expenses." It is of course on account of the limited revenues that scientific management is the more necessary to accomplish the best results with the means at hand.

Among the subjects with which the report deals are: The principles and methods of staff organization; selection and training of employees; office location and arrangement; selection of office furniture, equipment and supplies; planning case record systems; filing; financial administration; and publicity methods. It includes a bibliography, and an appendix giving details of four record systems in use by different types of nursing organizations.

ECONOMIC LOSS DUE TO POOR VISION.

The Eye Sight Conservation Council of America publishes the following facts:

The value of your eyes—the sense of sight—cannot be expressed in any terms. Next to life itself, is vision, and yet millions have defective

eyes. The great majority are unaware of impaired vision and do not know that theirs is less than a full measure of the most valued of the senses. Many others do not understand that a considerable degree of the vision they do enjoy is gained only through nerve exhausting eye strain.

Looking at this condition from a purely economic angle, one is appalled at the resulting waste of effort and the inefficiency of millions who daily contend with the handicap of faulty vision.

Recent studies show some startling results.

In the examination of more than 10,000 employees in factories and commercial houses, 53% were found with uncorrected faulty vision, 13% had defects which were corrected, making a total of 66% with defective eyes.

In one manufacturing establishment over 70% were found with eye defects.

In another plant the following startling condition was discovered:

Glasses worn and satisfactory....	8+	%
Glasses needed and ordered....	83+	%
No glasses needed.....	8+	%

As an example of inefficiency and resulting waste, 20% of the inspectors in a large factory were found to be unable to see *sufficiently well* to detect defects in the product they were inspecting. This is an intolerable situation and inexcusable when the remedy is so simple and inexpensive.

There are 42,000,000 gainfully employed in the United States—over 25,000,000 are handicapped by defective vision or eye strain.

THE EFFECT OF THE NATURE OF THE DIET ON THE DIGESTIBILITY OF BUTTER.

Arthur D. Holmes is the author of a paper published in *Science* for June 22, 1922, and gives his conclusions as follows: It is evident that dairy butter is very completely utilized by the human body. In those diets in which the accessory foods were very nearly if not entirely absorbed by the human body, butter was found to be practically completely digested. When coarser materials, particularly those which provided considerable refuse, were included in the diet it was found that butter was somewhat less completely absorbed by the body. The general conclusion to be drawn from the results of the digestion experiments is that butter eaten in conjunction with ordinary food materials is very completely digested and that for the diets studied, the nature of the diet does not produce a marked difference in the amount of butter absorbed by the human body.

NEW REGULATIONS TO RESTRICT LIQUOR BLANKS.

New regulations further limiting the use of liquor prescriptions by physicians are said to be in preparation by the Treasury. It is said they will accord with the Willis-Campbell bill prohibiting beer as a medicine and limiting the alcohol which may be prescribed to one-half pint in ten days and the number of prescriptions allowed to a physician to 100 in three months. The Treasury is understood to be considering a change in the definition of a liquor prescription to extend that classification to cover prescriptions issued for medical compounds of which alcohol is an ingredient as well as a prescription for a regular alcoholic liquor.—*Illinois Medical Journal*.

MEDICAL LITERATURE FOR RUSSIAN PHYSICIANS.

Famished Russian physicians are hungrier for modern medical literature than for bread. Dr. Henry Beeuwkes, chief of the medical division of the American Relief Administration, says that requests for English and American medical journals are constantly pouring into his office, and that these requests are as urgently pressed as the applications for food packages. In fact, in some cases more urgently.

"Any American physician who has files of medical journals for the past three years to dispose of," said Dr. Beeuwkes, "could confer no greater boon upon the medical fraternity of Russia than to turn them over to the American Relief Administration for distribution here. Many of the Russian doctors have not seen a medical journal from the outside world for years."—American Relief Administration.

FLIES.

IN order to carry weight to the argument that the fly should be eliminated, the housekeeper should be told that the fly is more dangerous than the man-eating tiger. In all probability, the house-fly has caused more deaths than all wild animals. Although the subject of fly extermination has been exploited, people are not yet fully impressed with the important rôle played by the fly as a factor in the production of disease. If our eyes could see the dirt and germs on the feet of the fly we would be more deeply concerned.

ENDORSEMENT OF THE HON. LESTER H. VOLK'S RESOLUTION. The Philadelphia Association of over seven hundred retail druggists has unanimously endorsed House Resolution No. 258.

PUBLIC HEALTH LECTURERS FOR THE YEAR 1922.

The Committee on Public Health of the Massachusetts Medical Society has been able during the past three years to arrange with well known specialists in various medical fields to give talks at meetings of the District Medical Societies on subjects of interest and importance to all practitioners. It is a pleasure to announce that a similar arrangement has been made this year and that the gentlemen named below are willing, without expense to the District Society, to give occasional talks of thirty to forty minutes on subjects relating to the promotion of public health, extending opportunity for questions and discussion. It is suggested that medical societies consider meeting at neighboring public institutions, since such meetings have been most successful in the past, particularly at the tuberculosis sanatoria and state hospitals for the insane.

José Penteadó Bill, M.D., Doctor of Public Health, Specialty: Preventive Medicine.

Frank C. Dunbar, M.D., Bacteriologist, Instructor in Bacteriology and Pathology, Tufts College Medical School.

Walter E. Fernald, M.D., Superintendent, Massachusetts School for the Feeble-minded.

Timothy Leary, M.D., Professor of Pathology, Tufts College Medical School; Medical Examiner, Suffolk County.

Edwin H. Place, M.D., Physician-in-Chief, South Department, Boston City Hospital. Specialty: Contagious Diseases.

C. Morton Smith, M.D., Chief of Department of Syphilis, Massachusetts General Hospital.

George Gilbert Smith, M.D., Assistant in Department of Genito-Urinary Diseases, Massachusetts General Hospital. Specialty: Genito-Urinary Diseases.

Lesley H. Spooner, M.D., on Staff of Out-Patient Department, Massachusetts General Hospital, Specialty: Specific Diagnosis and Treatment of Pneumonia.

William C. Woodward, M.D., Ex-Health Commissioner, City of Boston.

George H. Wright, D.M.D., Lecturer on Dental Hygiene, Harvard Dental School. Specialty: Dental Surgery.

Thomas F. Kenney, M.D., Director of School Hygiene, City of Worcester. Specialty: Full time School Health Officer.

Secretaries of District Medical Societies writing to ask for these lecturers will kindly designate the topic, the place and the hour of meeting as well as the name of the desired speaker, thus eliminating unnecessary correspondence. Please address communications to the Secretary of the Committee, Annie Lee Hamilton, M.D., 164 Longwood Ave., Boston 17.

[Note: The Committee on Public Health feels that this notice may have escaped attention, for few applications have been received. Each lecturer is an authority and would present his subject in an interesting and instructive manner.]

Address.

THE PRESIDENT'S ADDRESS AT THE ANNUAL MEETING OF THE MASSACHUSETTS TUBERCULOSIS LEAGUE.

APRIL 21, 1922, BOSTON.

By EDWARD O. OTIS, M.D., BOSTON.

Not long ago the question was asked by one of our local associations what advantages they obtained from the League by being a member of it and contributing a portion of their Christmas Seal Sale income for its support. This is a fair question, for everyone wants to feel that he is getting his money's worth, and I shall endeavor to answer it. In all I have to say I shall assume that the League is wisely and efficiently conducted, and its income economically expended, and that it always endeavors to act for the best interests of its component parts—the local associations. Further, I may make the preliminary remark that in all organizations there must be a reciprocal relation between the parts and the whole—a giving as well as a taking. In the first place it is obvious, I think, that any undertaking with a similar object in view, whatever its character, gains strength, solidity and prestige by the union and co-ordination of its component parts, each local organization at the same time retaining its own autonomy and carrying on its own special work. By becoming, however, a member of the larger unit, in this

ease the State League, there are many ways in which the local association may gain aid in its work, and in turn aid the State Organization by its influence and experience.

As you know the State Associations are members of the National Association and, in consequence, each local association becomes *de facto* a member of the great National body, one of the most efficient of its kind, it has been said, in the world. This National Association is constantly developing new methods and programs for the most effective procedures in the tuberculosis warfare, all of which, through the State League, are at the service of the local associations. The National Association offers methods of publicity, administration, field, educational and medical expert service and conducts research work. Through the State League the local bodies share the fruits of the National body as well as contribute their parts to its success. We could not, indeed, carry on the Christmas Seal Sale without the aid and direction of the National Association, for it has become such a vast undertaking that only the larger body could successfully inaugurate and finance it.

Again, a State organization can obviously take a wider view of the whole State problem of tuberculosis and better appreciate what is needed. It is in a position to suggest and advise general policies and methods for local bodies so that they may most effectively solve their own local problems and most wisely and economically spend their money. This the

League is constantly called upon to do. It is the League which represents its component organizations in legislative matters, both in safe-guarding its own special field of health work and in advocating good and opposing vicious health legislation. For example, through its representatives it advocated the light-saving law and more accommodations for non-pulmonary tuberculosis, a bill which is, I believe, now before the Legislature.

In all philanthropic movements we are dependent upon public sentiment and public good will, and this can best be obtained and crystallized by bodies which are both State and nation-wide in which the public have confidence. It is the one large State association that the public look to for information and guidance in the tuberculosis campaign. In any undertaking nowadays publicity is of utmost importance, and it is the State League which must and does do this for the State, as the National Association does it for the Nation. Although each local association has its own peculiar problems, there are certain general lines of work common to all, such as a tuberculosis survey, expert diagnostic service, tuberculosis nursing, etc., and such common service the League endeavors to provide and render effective. "None of us liveth to himself" for we all realize sooner or later that the satisfactory and satisfying life is one of service. Although the larger and better organized local associations have less need for direct service from the League than the smaller ones, and may feel that they are sufficient unto themselves, and are rather reluctant to contribute their percentage from the Seal Sale to the League, yet is it not worth while to feel that a part of their contribution is being used in the aid and support of some weak and struggling association in a community which could not obtain sufficient resources itself for work needed to be done in its midst?

Again, the office of the State League is a general clearing house for all sorts of information, appeals and complaints. Thither comes nurse, tuberculosis worker, doctor or layman, interested in some phase of tuberculosis work; all wanting information, advice or guidance in their especial problems. Furthermore, the Executive Secretaries are constantly going about the State visiting the local associations, learning from some, stimulating and advising others, and setting on their feet those who have fallen down and ceased to function. Perhaps, it is not generally known that several times a year the Executive Secretaries, of all the New England Associations, meet together to discuss general tuberculosis problems and to exchange their experiences, and such meetings are very fruitful in gaining new viewpoints and in solving many problems in State tuberculosis work.

Each secretary gains new ideas and valuable suggestions and these rebound to the benefit of the local associations.

Through its committees the League is constantly studying various phases of tuberculosis and health work, such as the standardization of surveys, the education of tuberculosis nurses, the care and provision for those suffering from non-pulmonary tuberculosis, and health legislation.

Last year the League made a small appropriation for research work in the study of tuberculosis among children under the direction of Dr. Maynard Ladd in the large Children's Clinic of the Boston Dispensary, the object being to determine the amount of tuberculous infection in children, from infancy to adult age, and the best means of preventing this infection from becoming active disease. In this connection there was a study made of excised tonsils to determine what proportions were infected with the tubercle bacillus. Already valuable data have been obtained and it is hoped that this research work may be continued if our funds will permit. As I said in the beginning I have assumed that the executive management of the League is active, efficient, intelligent, progressive, and economical with the funds entrusted to it, and of this you, the local associations, are to be the judges, for the League is your servant.

Finally, and in a brief sentence, the State League exists for the purpose of studying and promoting the best and latest methods for carrying on the anti-tuberculosis work in the State and in so doing promoting the public health.

If the League is an important instrumentality in combating tuberculosis, as I have endeavored to show, and is to be a continuing body, then it must receive adequate support and not be dependent entirely upon the more or less uncertain income from the seal sale. Why should we not seek an endowment? More than one of our local associations have received legacies, and why should not the League which is soon to be incorporated, appeal to the public for means to place it upon a solid basis? What more appealing object than the prevention of tuberculosis? Tuberculosis is, and is likely to remain for an indefinite number of years to come, a very prevalent disease. All fear it and all, directly or indirectly, have suffered from it, and all should lend a hand in its suppression.

The State, as well as the counties, are spending large sums for the care of tuberculous adults in their various sanatoria, but the tuberculous children are being neglected, and tuberculous children respond so quickly and satisfactorily to treatment. We need one or more sanatoria exclusively for children. Connecticut, for example, has two such institutions, one

on the seashore and one inland, where heliotherapy is being employed with striking success. France has for years maintained large seaside sanatoria for children and so have other European countries. I have only to refer to the admirable results obtained by Dr. Chadwick, at Westfield, to indicate the extreme value of sanatoria for children. The League, it seems to me, might well undertake a propaganda to influence public opinion in favor of greater accommodations for tuberculous children. For children suffering from bone and joint tuberculosis sea-side sanatoria have been found particularly favorable, and it is to be hoped that in making provision for non-pulmonary tuberculosis, as is now contemplated by the State, provision will be made for a sea-side institution for children suffering from non-pulmonary diseases.

An interesting incident was told me the other day of a little girl who was sent to the Connecticut sea-side sanatorium strapped to a board, suffering from spinal tuberculosis. She recovered from this, but meanwhile developed pulmonary tuberculosis. She was then transferred to the inland sanatorium where she recovered from her pulmonary affection and is now a robust, healthy girl. Such is the resiliency of childhood!

The public are beginning to realize that prevention is better than cure, and as I shall show later, this is especially true with regard to children, hence so-called preventoria are coming into existence. There is one connected with the Sharon sanatorium, and the Boston Tuberculosis Association is about to open one at the Prendergast Camp. In Toronto there is a flourishing institution of this kind, of which some of us have heard through Dr. Elliot, and a number of others elsewhere. Such preventoria are equally valuable for young adults. At St. Agathe, in the Laurentian Highlands of Canada, is such an institution for young women of depressed physical condition. Who can estimate the value of such institutions and the number of active cases of tuberculosis prevented by this timely aid? The economic saving to the community of such preventoria is obvious. It is so much cheaper to prevent the child and young woman from developing tuberculosis than to try to cure them after the disease has become manifest. Here is another object for a League propaganda — the establishment of preventoria in the State, and I am sure they will come in the near future.

Medical Social Service, introduced some years ago through the genius of Dr. Richard Cabot, has abundantly demonstrated its usefulness, and has become an established institution in the best hospitals and dispensaries. Anyone who has worked in a clinic with an accomplished, wise, and sympathetic social worker, knows how inval-

uable her services are in dealing with tuberculosis. She is, indeed, a ministering angel. Some State sanatoria include in their personnel such a social worker, and we should in ours, which, I believe, at the present time is not the case. The psychic treatment of a tuberculous individual is often quite as important as the medical, but the medical attendant has not the time and, perhaps, not the talent or experience to minister to a mind distressed or worried. Unless the mind is at rest, and free from anxiety, the physical condition will not only not respond to treatment, but will retrograde, as Dr. Waters, of the Loomis Sanatorium, has very cleverly shown by the comparison of x-ray plates of a tuberculous patient, taken at varying intervals, which showed evidence of advance of the disease when the patient had been worrying over some unfavorable news from home. A word of sympathy, a bit of comfort, a sympathetic attention to the story of an overburdened heart, from the social worker may accomplish more for a lonely, discouraged, worried sanatorium patient than any medical treatment can do. In this materialistic age we, and I include the doctor, are too apt to "mind the things of the flesh" and ignore "the things of the spirit." It is often easier to treat a bodily pain than to soothe a troubled mind, but to remedy the latter may result both in health and happiness. "It should be the special business of the social worker," says Dr. Cabot, in referring to tuberculosis, "to point out that not for economic, but for spiritual reasons, it is a dangerous experiment to take a man away from his work and put him on his back in a steamer chair for months at a time."

As you are aware, much has been said and written regarding the discouraging results of sanatorium treatment. At first we thought the tuberculosis problem was well on the way to its solution, when the sanatoria came into existence and patients were discharged "cured," as we then labeled them. Time and experience, however, have taught us that sanatoria effect but little the incidence or prevalence of tuberculosis, and the best we can say now, regarding a patient who seems to have recovered, is that his disease is "arrested." Even of these "arrested" cases a certain proportion relapse and still more of the "improved" cases; and with every relapse the money expended in the treatment is wasted. From all this it is apparent that more after-care and supervision is needed. For each patient discharged from the sanatorium there should be someone whose definite duty it is to keep him under supervision. If not otherwise provided by the State, why could not the local associations undertake the responsibility of following up those patients who belong to their community? The problem of obtaining work for the arrested case of tu-

bererculosis is a very difficult one and, as you know, many plans have been suggested but none so far have proved practical upon a self-supporting basis. At present not a few industrial establishments seem willing to take for part time, or for light jobs, these arrested cases. The Boston Tuberculosis Association undertakes to find such employment for these persons, and other associations might well follow their example. We must recognize the fact that when the tuberculous individual is discharged from the sanatorium the work is but half done. He must be followed up, by visiting nurse, social worker, or some competent person, and if able to work effort must be made to obtain such suitable employment for him as will not jeopardize or undo the gain or arrest he has obtained from his sanatorium treatment. Otherwise, the money spent for such treatment is likely to be an economic loss.

Some years ago President Eliot, in an address on "The Coming Changes in the Medical Profession," said that the probability was that the greater part of the work of medical men was, hereafter, to be done in preventive medicine. We may consider this a prophecy of perfection rather than a realizable attainment, for we shall always need the individual services of the physician for our individual need, in the chances and changes of this mortal life. There has been, however, an increasing and pronounced appreciation, on the part of the public, and of the medical profession as well, of the supreme value of preventive medicine or, to use a better term, of the prevention of disease. As Dr. Robertson, the late Commissioner of Health of Chicago, says, preventive medicine is the intelligent demand of a now intelligent public. The presumably well are now seeking, or being asked to have a medical examination, to see if they are really as well as they think they are, and are in physical condition for their self-imposed or directed duties, and if their habits of life are consistent with continued well-being. We have, for example, the "Life Extension Institute," and the so-called "Health Clinics," a notable example of which is now conducted at the Boston Dispensary. Expectant mothers are kept under observation to prevent certain disasters incident to that condition. We require vaccination to prevent smallpox, and advocate the Schick test for children, and the toxin-antitoxin injection, if this test is positive, to prevent diphtheria. We employ the anti-typhoid vaccine to prevent typhoid fever. And experimental work is now being done to discover a vaccine to prevent pneumonia. The American Society for the Control of Cancer urges frequent physical examinations in order to detect malignancy in its earliest stages and thus prevent its development into a hopeless condition. It is becoming increasingly the custom in large

industrial concerns to examine the employees when they enter the industry and periodically thereafter. We have the medical examination of school children and of academy and college students. In Massachusetts, and I know not how many other States, an examination is required, of children of 14 to 16 years of age, before they can enter an industry, in order to prevent the development of any weakness into disease. You will recall that President Roosevelt instituted periodic examination of the officer personnel of the army who were presumably well, and the present Surgeon-General of the army declares that he firmly believes in periodic examination of the civic population.

According to Dr. Haven Emerson (*Journal of the American Medical Association*, March 25, 1922, page 901), an increasing number of people attend the cardiac clinics in New York City to find out whether or not they have cardiac disease, and not how they may be cured when they have heart disease, and Dr. Emerson says that there has been set up by the Academy of Medicine, of New York, a series of examining stations where physicians examine people, who are presumably well; health clinics we should call them. There are now classes for the examination of the mental capacity of persons of various ages to prevent mental disease or regulate the mental habits of the individual. The same authority (Dr. Emerson) states that in the thirty-one tuberculosis clinics of New York City, in the last 15 years, one million people have been examined, and in the year 1921 66 per cent. of the people who went to clinics were found to be non-tuberculous, the percentage having risen from 20 per cent. to 66 per cent., a million of the population. Hence, it is evident that an increasing number are being examined to find out the condition of their lungs, not that they suspect or have symptoms of tuberculosis. When we consider all these already existing instrumentalities for preventive medicine we must confess that President Eliot's prophecy is well on the way to fulfillment.

The experience in the great war is familiar to us all, where a surprisingly large number of physical defects were discovered, hitherto unsuspected, in supposedly well young men. This experience has impressed the public, I believe, as to the prophylactic value of health examinations and health clinics, and with but little urging, I believe, the people would eagerly seek such physical examinations. One of the most important parts of such a health investigation is a thorough examination of the lungs of presumably well persons. To be sure, we as tuberculosis workers have always made prevention an important part of the campaign against the disease, but in the past we have largely confined our efforts to the prevention

of the spread of the tubercle bacillus. Should we not now make a more pronounced effort to persuade the *well* to have an examination of their lungs, and should we not join with other health organizations in the rapidly increasing movement in the prevention of disease? You will recall that in the Framingham Health Demonstration all the inhabitants were offered and urged, to have an examination of their lungs, and important results were obtained thereby in the discovery of unsuspected pulmonary disease. Why could not the clinics, now held by the experts of the State Board of Health, enlarge their functions, and offer to everybody who wishes it an examination of the lungs and urge the importance of so doing? So long as pulmonary tuberculosis still continues to be one of the most prevalent and dreaded diseases of modern times the advantage of such examinations, both to the individual and the public, is obvious. The most successful means of preventing tuberculosis is to prevent its happening. Still better it would be if the tuberculosis expert should join with experts in other departments of medicine and hold health clinics which would include a complete physical examination. When once the public recognizes the supreme value of such health clinics, there will be no dearth of applicants.

"One thing necessary," says Dr. Wightman, of the Chicago Municipal Sanatorium, "for those who would be well is an annual physical examination. It is only by means of such examinations that the doctor is able to prevent the development of disease. The intelligent have already learned that if they go often enough to a good dentist he will prevent any serious dental troubles from developing. The same class of people will soon know that if they go often enough to a good doctor (or to a health clinic) any serious physical trouble will be prevented from developing." We must persuade the thoughtless majority, who consult the physician only when they have an ache, or a pain, or feel ill, to recognize also the value of periodic physical examinations to prevent the pain or illness, and to have their lungs examined to prevent tuberculosis.

THE MANAGEMENT OF CANCER OF THE BLADDER.*

By GEORGE GILBERT SMITH, M.D., F.A.C.S., BOSTON.

THE management of cancer of the bladder is rather a complex problem, inasmuch as the methods of treatment vary widely according to the type of growth. In discussing this ques-

tion, it seems to be necessary to start with a brief review of the pathology of vesical neoplasm, and to attempt to separate the lesions into classes more or less according to the kind of treatment which each class requires.

For the point of view of the pathologist, let us turn to the 1922 edition of Ewing's book on "Neoplastic Diseases" (p. 860 *et seq.*). There we find the epithelial tumors of the bladder classified as follows: Papilloma—fibrous; benign; malignant. Carcinoma—adenoid (rare); diffuse. We are justified in including the papillomata among cancers of the bladder, for all papillomata are potentially malignant. They consist of a connective tissue framework, more or less branched, covered with a layer of cuboidal epithelial cells. It would be impossible to say whether any particular papilloma was malignant unless one could examine every bit of it microscopically, for some parts may appear entirely benign, while in other areas the cells show a method of growth, a heaping up and a breaking through the basal membrane, which is characteristic of carcinoma. Ewing says that 25 per cent. become malignant; Frisch reports three cases in which the removal of a simple papilloma was followed by the development of single or multiple carcinomata. Ewing states, furthermore, that "the microscopic structure usually indicates considerable growth capacity which in other situations would always prove malignant. The clinical malignancy is also influenced by the tendency of new tumors to develop progressively in a predisposed mucosa" (pp. 861-2). This evidence should be enough to warrant the inclusion of simple papilloma in a paper on cancer of the bladder; a papilloma which shows necrosis is practically certain to be malignant.

The career of a papilloma is interesting. It may exist for years without undergoing much change, causing either no symptoms or a painless hematuria, and suddenly it may start to grow rapidly and acquire malignant characteristics. I have never seen a benign papilloma reach a size larger than perhaps two cm. from stem to tip. The larger ones have either been proved to be carcinoma by the microscope or have shown, by their recurrence as a definite cancer, that they were indeed malignant. Ewing says that 75 per cent. of all papillomata reach an urgent condition or are fatal in three years.

Malignant papillomata, or papillary carcinomata, may grow so large as to fill the bladder. Clinically they appear as round, partially necrotic tumors which bleed very easily. Although they appear solid, their tissues are as friable as a piece of blood clot. Their cells are easily transplanted to other parts of the bladder, or to the operative incision. They are attached to the bladder wall by a thick pedicle,

*Read at a meeting of the Essex North District Medical Society, May 3, 1922.

or sometimes by a broad infiltrating base. Often multiple, the smaller ones appear through the cystoscope as low, bushy growths which are attached firmly to the bladder wall, and do not wave in the current as do benign papillomata.

Malignant papillomata often become encrusted with phosphatic deposits and infected, thereby setting up a severe cystitis.

Bueger believes that of all cancers of the bladder, from 30 to 36 per cent. originate as papillomata.

Those growths which have not this origin develop directly in the bladder mucosa. They may assume a glandular form, if derived from the mucous glands of the bladder, but this type is rare. The common form is a sessile growth, very firm to the touch, sometimes covered by intact mucosa, but more often slightly ulcerated. Occasionally the ulceration is more marked with elevated, indurated margin. Some writers divide these into transitional or squamous cell cancers, but this distinction is of little practical importance.

These growths are less likely to be accompanied by infection. As they progress, they may show proliferative changes; in this stage infection is frequent. The growth extends through the bladder wall into the perivesical tissues and to the regional lymph glands. Both Ewing and Judd remark upon the slowness with which cancer of the bladder metastasizes to distant points. I have seen two cases recently in which distant metastasis occurred—once in the third lumbar vertebra, and once in a supraclavicular gland. From my own experience I would say that metastases in the spine were not at all uncommon.

By far the most important factor in the successful treatment of cancer of the bladder is early diagnosis. Unfortunately one sees a number of cases in which the diagnosis should have been made months, or even years, before. Such occurrences are a disgrace to our profession; every case of hematuria in which the bleeding is not due to an obvious cause should be cystoscoped. The omission of this simple and easily available test in a case of symptomless hematuria is as indefensible as the failure to give antitoxin in a case of diphtheria. Every case of hematuria and every case of irritable cystitis unaccounted for by obstructing prostate or by urinary tuberculosis should be suspected of cancer, especially if the patient is above 30 years of age. If the urine has a peculiarly foul odor, suggesting decayed tissues, the diagnosis can be made, almost for certain, without further examination.

Observation cystoscopy, which is today, thanks to the small calibre of the modern cystoscope, a very simple procedure, will give the diagnosis and will tell us with which type of growth we have to deal. If the bleeding is

excessive, it may be necessary to place the bladder at rest for a week or so by an indwelling catheter; if this is done, with the aid of adrenalin solution instilled into the bladder, a fair view can almost always be gained. A careful general examination should be made. Bimanual palpation of the bladder with a finger of one hand in rectum or vagina and the other hand making pressure above the pubes, will give valuable information as to the presence of induration within or about the bladder. Search should be made for glandular masses within the pelvis or upper abdomen. An x-ray of the spine is useful in certain cases. The age and general condition of the patient must be taken into consideration, and an estimate made of his probable vitality and ability to resist infection.

When, by careful study, the surgeon has discovered with what type of lesion he has to deal, he must decide upon his method of attack. There are the surgical measures of cystostomy with canterization; permanent cystostomy, partial resection of the bladder, and total cystectomy. There are the measures possible to employ without opening the bladder, such as fulguration and the application of radium. There are various combinations of these.

Let us now turn to the treatment of the several types of growth encountered in the bladder. Simple papilloma is delightful to treat. Practically all of these, if they are really not malignant, respond readily to fulguration, or destruction by means of the high frequency spark. Through the cystoscope the electrode is pressed against the tumor and the current turned on. Bubbles of gas rise from the point of contact; the tumor for a millimeter or two about the electrode tip blanches and shrivels up. If the tumor is small, the stalk may be cut across directly; if larger, it is destroyed at several sittings. Malignant papillomata do not respond so well; if, therefore, the tumor is easily destroyed, the chances are that the mucosa at its base is not involved. The largest papilloma which I have destroyed by fulguration was the size of a small plum.

There is, as Ewing states, a predisposition on the part of the mucosa of such bladders to form papillomata. Sometimes the recurrences will be definitely malignant. It is essential, therefore, to cystoscope these cases frequently so that recurrences may be detected while small and be given appropriate treatment. I have the patients return every three months for the first year, then every six months for two more years; after that, once a year.

Let me give a few illustrative case histories: F. E. H., a traveling salesman of 46, came to me in April, 1915, with the story that six months previously he had noticed a little blood at the end of urination. This ceased almost entirely, but the week before his visit to me

the urine was bloody throughout. The force of his stream had been lessened. Cystoscopy showed a good-sized, filamentous papilloma arising from the right ureteric ridge, hiding the orifice of the ureter. This was completely destroyed by nine fulguration treatments. February 23, 1916, cystoscopy showed no recurrences. August 22, 1916, one tiny bud back of the right ureter was discovered and destroyed by fulguration. December 28, 1917, cystoscopy showed no recurrences. Since then the patient has not returned for cystoscopy, in spite of a letter asking him to do so.

G. A. D., a plumber of 34, consulted me August 20, 1919, because of hematuria which he had had constantly for one year. Cystoscopy showed a papilloma the size of a bean rising from the left ureteric region. The tumor and the mucosa from which it arose were destroyed by three fulgurations. Cystoscopy in June, 1920, showed no recurrence. January 20, 1921, a tiny bud was seen upon the left side of the trigone and was destroyed. There was not even a scar left to mark the spot where the original tumor had been.

Inasmuch as the recurrent papillomata which I have seen have usually risen from a different area than that upon which the original growth was situated, it seems reasonable to assume that they would have developed, no matter whether the tumor was excised or was destroyed by fulguration. The destruction of simple papillomata by the latter method, therefore, seems to me to be without question a better procedure than radical operation. If the tumor is bushy or necrotic, the question of treatment is a different matter. The tumor then is probably malignant; consequently there is a likelihood of involvement of the bladder mucosa at its base, and the removal or destruction of the bladder wall at this point is indicated. If the tumor is so situated that it can be excised together with the entire thickness of the underlying bladder wall, this operation should be done. If the tumor arises from the trigone or the vesical sphincter, thereby making its thorough removal very difficult, or if the patient is not in condition to stand a long operation, the bladder can be opened, the tumor destroyed by the cautery, and radium implanted in the bladder wall in such a way as to slough out the tumor-bearing area. In case any operation is contraindicated by the patient's condition, or if the tumor is a recurrence following a previous operation, so that one does not feel it advisable to operate again, one may implant bare tubes of radium emanation in the bladder wall beneath the growth by means of the operative cystoscope and a flexible, needle-pointed "drill." One or two of these tiny glass tubes, or "seeds," are deposited in the tissues and left there. Each seed should be of low potency, from one to three mc.; the beta and gamma rays given off

will destroy the tissues over an area 1.0 cm. in diameter, and at the end of a week the seed will have lost its radioactivity.

We come now to the question of treatment of the more extensive cancers of the bladder, both of the degenerated papilloma and of the sessile cancer type. It may be said at this point that when cancer of the bladder has reached a certain point, there is no method of treatment yet discovered which will avail. At the Huntington Hospital we occasionally have such advanced cases sent in for radium treatment; when the bladder feels like a cannon ball and the pelvis contains great masses of cancerous lymph glands, there is no help for the patient.

Certain cases, however, may appear to be quite advanced when the interior of the bladder is viewed through the cystoscope, and yet may be amenable to the right sort of treatment.

We may divide the more extensive cancers of the bladder into two classes, the localized and the diffuse. The former are more deeply infiltrating, more scirrhous, and slower of growth. They are less likely to be accompanied by severe cystitis. All these points are factors in influencing our selection of a course of treatment. If the localized cancer is situated high up on the lateral wall or upon the dome of the bladder, and does not appear to have penetrated the bladder wall, a wide excision is the best procedure.

C. K., a woman of 55, came to the Massachusetts General Hospital with a history of having been passing clots of blood in the urine for the preceding two weeks. Cystoscopy showed a growth on the right lateral bladder wall, including the ureteral orifice. In July, 1920, I excised a solid tumor the size of a small plum; the entire thickness of the bladder wall was removed, including the orifice of the ureter. The resected ureter was reimplanted in the bladder. As the growth appeared to involve the entire thickness of the bladder wall, the perivesical tissues upon the right were given radium treatment; 25 mg. of radium element, screened by one mm. brass and one mm. rubber, was placed at the bottom of the perivesical sinus one week after operation and left in 24 hours. The patient made a fairly good recovery and in October, 1920, felt quite well. Cystoscopy showed a mild cystitis, but no evidence of recurrence. The orifice of the implanted ureter could be seen as an oval slit which opened and closed much like a normal orifice. January 28, 1921, cystoscopy; the same findings. In March the patient began to have sharp pains in right knee, thigh and lower back. Pelvic examination showed no induration and no glandular masses. The back pains became worse; they were evidently due to metastasis. The patient rapidly failed, and died, about one year after operation, with metastasis in the lung.

A good many of these localized cancers are situated close to the prostate or down in the funnel of the bladder neck, so that excision, and particularly closure of the bladder wall to fill the defect, is almost impossible. In such cases the implantation of radium gives the best results.

As this method of treatment is fairly new, and is, moreover, one in which I have been extremely interested, I shall digress from the main theme for a few moments to go into the question of radium treatment in some detail.

From our experience at the Huntington Hospital we have come to the opinion which I think is now held by most genito-urinary surgeons, that it is next to useless to treat infiltrating cancer of the bladder by radium introduced into the bladder and applied, more or less accurately, to the growth. The cancer, to be destroyed, must be sloughed out, and the best way to accomplish this is by means of radium implanted directly into the tumor. The means of radiation may consist of needles containing radium salt, in which case a number of small needles, of 5 mg. each, are preferable to fewer large ones; or it may consist of little glass tubes containing radium emanation. If the needles are used, they should be inserted about one cm. apart and pulled out by means of, thread after 24 or 36 or even 48 hours, according to the amount of radiation desired. If the emanation tubes, or "seeds," are used, they are abandoned in the tissues. In either case the effect is substantially the same. Close to the needle or tube the tissues become completely necrotic; further away there is a zone in which the cancer cells are killed but not sloughed out. Beyond that is a zone in which infiltration with leucocytes and fibroblasts takes place, forming a barrier of dense connective tissue. The center of the growth, where the rays from the tubes cross each other in all directions, sloughs away. Around the periphery there is found a barrier of connective tissue which prevents the spread of cancer cells by way of lymphatics. The process of destruction and repair takes from two to six months, depending upon the condition of the patient and the extent of the reaction. Infection may supervene, and sometimes causes the death of the patient.

The application of this method to bladder cancer is limited to those cases in which the area to be radiated does not exceed 3 or 4 cm. in diameter; if larger growths are radiated, the extensive necrosis is likely to prove more than the patient can stand.

Of the earlier cases which we treated by this method, several died in from six weeks to three months after operation, and in one case eight months later, apparently from the toxic absorption or from renal infection consequent upon the bladder condition. In half a dozen cases, about half of the number treated in this way,

excellent results were obtained. One case will illustrate this class.

A. Y., 65, carpenter, seen August 5, 1920. Complaint: Hematuria for eight months. Cystoscopy showed an extensive ulcerative growth, with elevated edges and necrotic center, on left lateral wall of bladder, not much influenced by application of 450 mc. of radium intravesically. Operation on February 10, 1921. Cystotomy; slightly ulcerated growth, about 3 cm. in diameter, found in left lateral wall of bladder. Induration seems to extend through bladder wall and is palpable by rectum. Piece excised for examination proves the diagnosis; whole tumor lightly cauterized. Twelve seeds of from 1 to 4 mc., total 32 mc., implanted in growth. Convalescence uneventful, except for epididymitis. No marked radium reaction. April 28, 1921, urine very dirty. Frequency every one or two hours. Slough which formerly covered left side of bladder has almost entirely cleaned up. June 30, 1921, patient gaining weight. Feels well. Cystoscopy: area of tumor almost entirely healed and covered with mucosa. August 18, 1921, back at work. Nocturia once. Cystoscopy: left wall of bladder practically healed. January 19, 1922, looks well and says he is in the best of health. Last night did not have to void at all and holds urine for three hours in day time. Urine slightly hazy. Cystoscopy: bladder clean and smooth. Prostatic outline shows definite adenomatous changes but is much less red than three months ago. In base of bladder, outside of left ureter, is a shallow fossa, the bottom of which is still covered with necrotic tissue. No evidence of malignant disease. To return in three months.

As was said above, the use of this method is limited to localized carcinoma. The diffuse, superficial type must be handled differently. One possible course is to open the bladder, cauterize all tumors found on thorough search, and into the bases of as many as possible implant one or two "seeds." Following operation, the patient must be cystoscoped at least every three months, and as recurrences develop they may be treated by intravesical measures, either fulguration or radiation.

Certain cases of this type will show too great an involvement of the bladder surface for this method to be employed. In these, the very radical operation of total cystectomy may be considered.

Cystectomy is an operation which should be done, I believe, much more frequently and much earlier than is now the custom. Given an individual in whom the question of recurrence is not a question but a certainty, who has nothing to lose and all to gain, who is in excellent general condition and shows no evidence of metastases, total cystectomy is an operation well worth serious consideration. About three years ago I operated upon a young

man of 29 for tumor of the bladder. A large pedunculated growth upon the trigone was removed and several smaller ones cauterized. The pathologist reported them as papilloma, but they showed necrosis and would, I felt sure, recur. I advised cystectomy, but the patient, not unnaturally, refused. Six months ago he consulted me again for pain in his back and cystitis. His bladder was full of cancer and he had undoubtedly a metastasis in the spine. He died soon afterwards. Cystectomy would have been a long shot for him, but had he gone through successfully he would very probably have been cured.

Last August, W. H., a man of 44, was operated upon for cancer of the bladder. Within three months the growth had recurred in a different part of the bladder; it grew rapidly, and it seemed that cystectomy was the only remedy. The situation was explained to the patient, who was a very intelligent individual, and he decided to take the chance. On January 2 of this year I implanted his right ureter into the ascending colon; three weeks later the left ureter was put into the descending colon. In February the bladder was removed. No enlarged glands or extra vesical extension of the growth was found. Had it not been for a rectal tear which I made in separating prostate from rectum he would have made a perfect recovery. As it was, a fistula resulted which took two months to close. The patient left the hospital early in April with only an occasional leakage through the perineum. Before his cystectomy he passed urine by rectum every three or four hours without discomfort and will undoubtedly do as well again after his fistula is firmly healed. During the time he was under observation in the hospital he showed no sign of renal infection, and his urine contained no pus.

Judd reports several cases of total cystectomy for cancer, one of whom was alive after 12 years.

The operation, in selected cases, will unquestionably save a number of lives and will prolong others in a comfortable condition.

CONCLUSIONS.

In this paper I have endeavored to show that all tumors of the bladder (barring some varieties, as fibromata) are potentially, if not actually, malignant; that early diagnosis by means of the cystoscope is the first requisite for successful treatment. Every misbehaving bladder should be considered guilty until it is proved innocent.

The methods of treatment consist of fulguration, radiation by means of implantation of radium, excision of the tumor, total cystectomy, or, in hopeless cases, cauterization and permanent suprapubic drainage. The particular measure or combination of measures selected

depends upon the type of tumor which is disclosed by careful study of the case. The results of surgery in cancer of the bladder are now far from satisfactory, improvement is to be expected only through earlier diagnosis, followed by more radical treatment in some cases, in others by the intelligent use of radium.

NUTRITIONAL DISORDERS IN THE LIGHT OF RECENT INVESTIGATIONS.*

By ALFRED F. HESS, M.D., NEW YORK.

ALMOST every generation or decade has its predominant medical interest. The most active subjects of investigation during the past generation have been those relating to infection. Today nutrition and nutritional disorders have become the central theme of medical interest. It is not difficult to trace the reason for nutrition having secured a position of priority. It was the natural sequence of a series of striking and far-reaching nutritional investigations which disclosed what may be summed up in the phrase "the importance of the minimal." It is unnecessary to recall the various instances where this principle has been found to hold true, and where the current conception of energetics has been shown to be inapplicable. We may cite as examples the essential importance for the animal body of certain amino acids and of traces of iodine. The discovery of the vitamins constituted a further step in this direction, adding fresh interest, as it disclosed an entirely new group of nutritional factors of vital importance for human welfare and existence, and associated with definite and well-established clinical phenomena. The recent war also tended to direct attention to nutrition; indeed, from a medical standpoint the World War differed from previous conflicts in that faulty nutrition and not infectious diseases proved to be its crucial problem. It furnished a demonstration, convincing to all the world, of the dependence of national vigor and health on the food supply. Furthermore, for the first time, governments were compelled to call upon nutritional experts for advice and to grant their decisions priority over those of high executive and legislative bodies. It seemed in place, therefore, before studying a particular instance of faulty nutrition—rickets, the topic of the next lecture to review critically some outstanding features suggested by recent investigations in this domain. A survey of this kind may have added value as the advance has been so feverish that there has been little time to pause and to reflect.

It is perhaps a commonplace that the most remarkable discovery in the field of nutrition

*Ottier Lecture delivered at Harvard Medical School, February 14, 1922.

within recent years has been the realization of vitamins and of their essential rôle. The time is not ripe for a discussion of the chemical nature and action of these attractive but elusive factors, but they may well serve as a text to illustrate certain points in connection with nutritional investigations. Before considering them from this point of view I should like to refer to one quality which two of the three established vitamins possess in high degree and which is of importance in connection with their presence in our food supply—namely, their marked sensitiveness to oxidation. I hope you will pardon also a short venture into the uncharted domain which deals with the fate of the vitamins within the body—for a hypothesis relating to the antiscorbutic vitamin, suggested by its destruction in an alkaline medium.

It has been demonstrated by Professor Hopkins for vitamin A, and at the same time by myself in relation to the antiscorbutic vitamin, that these factors are readily and rapidly destroyed by oxidation.^{1,2} For example, if three cubic centimeters of normal solution of hydrogen peroxide are added to a liter of milk, this suffices within a few hours to destroy entirely its antiscorbutic vitamin. Similar destruction results if orange juice or tomato juice is subjected to nascent oxygen. This peculiarity is responsible probably for the loss of potency of antiscorbutic foodstuffs through "aging"—a mere form of oxidation. It accounts also for the loss in the antiscorbutic factor which can be brought about by shaking fluids such as tomato juice. Another application of this principle furnished the explanation of why some found dry milk to retain its antiscorbutic potency, whereas others found it almost devoid of this factor. The milk which was tested in the former instance had been dried by the drum roller process, in the course of which it is subjected to but slight oxidation, whereas the milk which lost its potency had been dried after having been transformed into a fine spray and thus thoroughly oxidized. More recent experiments have shown that vitamin destruction by oxidation can be hastened by means of an addition of small quantities of copper to a foodstuff—by a catalytic reaction. This may be illustrated by the following experiment: Milk pasteurized in a glass container did not induce scurvy when fed to guinea pigs in 100 c.c. per capita amounts, whereas another lot of the same milk, which had been pasteurized in a copper vessel—and contained 1.4 part of copper per million—induced scurvy when fed in the same amounts. That the disorder was scurvy was evidenced by the prompt curative action of orange juice. When we consider the wide distribution of catalytic substances in food it would seem that this factor may at times diminish the potency of this vita-

mine. The broadest application of catalytic action is probably in connection with the pasteurization and condensation of milk which is carried out in copper vessels and pipes which are coated with a very thin covering of tin. As is well known, these containers are frequently worn, so that the copper comes into direct contact with the milk; in some instances they are not kept thoroughly clean. This is a practical aspect of the food supply which should be investigated further.

Nothing is known of the fate of the vitamins within the body. However, the clinical course of scurvy and our knowledge of the characteristics of its vitamin suggest certain deductions. As you all know, the antiscorbutic vitamin is protected from destruction by the acid reaction of food, and, on the other hand, undergoes more or less destruction when rendered even slightly alkaline, a result which is intensified by moderate degrees of heat. Experiments clearly demonstrating this behavior have been carried out for acid antiscorbutic foodstuffs, such as orange juice and tomato. La Mer,³ who has studied this question very carefully, was able by the addition of alkali to tomato juice to increase the destructive effect of heat as much as 22 per cent. It is evident, therefore, that gastric juice protects and preserves the antiscorbutic potency of food, whereas a lack of hydrochloric acid tends to destroy it. Have we not here a condition which may prevail in some cases of scurvy which develop in spite of what should be an adequate supply of the specific vitamin? Those who have followed the literature of scurvy must have been impressed by the authenticity of reports of this nature, which have been reiterated for centuries. It would seem a logical explanation of these irregularities that the vitamin has been destroyed within the body by prolonged contact with alkaline digestive juices. These baffling failures of antiscorbutic food have occurred generally in prisons or among soldiers living in damp and unfavorable surroundings, or among troops that were homesick, besieged, or in retreat. In other words, the experiences have involved individuals who were mentally depressed. For some time it has seemed probable that there is a psychic element in the development of scurvy; this aspect can be interpreted in part as due to a suppression of function of various glands in the body, especially the acid secreting glands of the stomach. From the broader standpoint such considerations indicate the range of aspects involved in these problems and particularly emphasize the inherent limitations of animal experimentation in affording a full understanding of human nutrition. A lack of secretion of hydrochloric acid is not the only condition which will tend to destroy the antiscorbutic vitamin within

the body. It is evident that unless this vitamin is absorbed quickly from the alkaline medium of the intestine it will be rendered inert. In the blood it again encounters an alkaline medium; in the tissues it is in addition subjected to destructive oxidative processes. These various conditions warrant the conclusion that this vitamin must exercise its action quickly within the body, and, furthermore, that it cannot be stored in the form in which it is ingested and is known to us. A corollary of these conclusions is that, unless it undergoes a rapid alteration to a more stable chemical state, its action would seem to be functional rather than structural.

One aspect which a study of the vitamins has brought into sharper relief than heretofore is the physiologic difference between man and the lower animals, as well as among the lower animals themselves, as to nutritional requirements. In relation to the antiscorbutic vitamin, man reacts as does the guinea pig; in respect to vitamin B, he reacts like the pigeon or the fowl; and in respect to vitamin A (fat-soluble factor), he resembles the rat. The rabbit, for reasons entirely unexplained, withstands deprivation of any vitamin with comparative impunity, and therefore is not employed in any biologic test for these factors. Furthermore, a diet which leads to a definite avitaminosis in one animal, leads to a quite different one in another animal. For example, a diet of polished rice brings about polyneuritis in the fowl or in the pigeon or in the rat, but induces scurvy in the guinea pig.* What are we to think of these peculiar vagaries? Are we to attribute them to divergent susceptibilities of the individual species, or rather to varying chemical reactions within the body? Whatever may be the answer, such divergent responses indicate and illustrate the fact that the metabolism of the lower animals and of man present far greater differences than have heretofore been acknowledged. They should caution against the practice of accepting unservedly, as applicable to man, nutritional experiments which have been performed merely on certain of the lower animals.

Another aspect that the recent studies of vitamins has served to elucidate is that foodstuffs should not be regarded as fixed chemical entities; that they vary greatly according to attendant circumstances. It is true that this was known to chemists from analyses of the inorganic constituents but its significance was not realized until it was evident how essentially different, from a biologic point of view, a food might be according to its content of vitamins. This distinction was first pointed out in rela-

tion to the antiscorbutic content of vegetables, which may be rich or poor in this factor according to whether they are plucked young or old, or whether they are allowed to age after they have been gathered. Of far greater interest is the fact, which many investigators have helped to substantiate, that the vitamin content of milk depends upon the vitamin quota of the ration of the animal; in other words, that animals are unable to synthesize vitamins. This fact has been demonstrated for all three established vitamins, and its significance and importance are obvious in regard to the diet of the nursing mother, of the cow or of other lactating animal.

We may well consider whether this point of view may not be extended to other constituents, whether the composition of the milk is not dependent on the diet more than is generally believed. For years, probably for centuries, the laity have held to the opinion that mother's milk could be altered by diet and that it could in this way be rendered harmful for the suckling. On the other hand, the tendency of modern medicine has been quite in the opposite direction, so that woman's milk has come to be regarded, from a clinical aspect, as a fixed entity, and its lack of compatibility has been ascribed rather to an idiosyncrasy of the infant. The exception has been the general viewpoint in relation to a varying fat content. Some physicians, however, have remained unconvinced by the negative evidence, trusting to the homely teaching of clinical experience. Of late several studies from the clinic and from the laboratory have led to the conclusion that milk may be rendered harmful by the entrance from the blood of an excess of normal constituents or of foreign substances. One of the most interesting of these reports is that of Shannon,⁴ who showed, by means of anaphylactic tests, that egg protein may be present in breast milk after the ingestion of a moderate quantity of egg, and that breast-fed babies may be sensitized to food which the mother has eaten, leading possibly to colic and indigestion. Howe's interesting work showing the absence of englobulin and pseudoglobulin from the blood of newborn calves and its sudden appearance after ingesting colostrum points in a similar direction.⁵ Hartwell's experiments on rats led to conclusions of a similar nature. She found that a diet containing a large amount of various proteins—egg albumen, blood albumin, edestin, gelatin, gluten—apparently rendered the milk poisonous and finally checked its flow.⁶ The toxicity of the mother's milk was evinced by convulsions as well as by loss of weight. Furthermore, Schick's⁷ recent demonstration of what he has termed "menotoxine" in the blood of some women during menstruation recalls the occasional disturbances in nursing infants

*Darling, whose opinion may be on the basis of his own clinical experience, writes: "A diet of polished rice in the African negro, in one laborer caused scurvy, in another, a time laborer, mild scurvy; and in some African women a diet that causes scurvy in one set of their children, in another

which have been attributed by the laity to this association. The cells of the mammary gland do not seem to possess the power of protective filtration with which they have been credited. Viewed from our knowledge of vitamins and other recent investigations, it would seem that milk is a far more varied biologic product than we have been wont to believe, both in regard to its physiologic and its pathogenic constituents.

One of the commonest fallacies is considering and designating the vitamins, particularly vitamin A, as growth factors. It is true that vitamins are especially needed during the growing period, as shown by their great abundance in young plants. There is, however, no single factor or group of factors to which this attribute should be applied. And it is well for man that this is so. In a particular instance an essential amino acid or an inorganic salt may prove to be the growth factor. I should like to illustrate this point by some recent experiences which have made it seem possible that a lack of iron may lead not only to anemia in infants but likewise to marked retardation of growth. In the case of some infants whose diet consisted of milk, but in some instances also of cod-liver oil, of orange juice and even of yeast—in other words, the three established vitamins in their most concentrated forms—no growth came about for many weeks. When, however, as little as two teaspoonfuls of spinach were added to the diet daily there was a prompt response of the

growth curve (Charts 1 and 2). McClelland and Sedgwick⁸ and also Berman⁹ have reported similar experiences. In these cases, had we not been supplying the vitamins in adequate amount, the sudden gain in weight might well have been interpreted as the result of the vitamins supplied in the spinach. This criticism is applicable to recent investigations on the effect of yeast on the nutrition and gain in weight of infants. Following the addition of the yeast to the dietary the infants gained, and it has been therefore concluded that this gain signified a former lack of water-soluble vitamin. But it was not evident that the dietary had been lacking in this vitamin. My own experience in this regard, embracing a large number of observations, has been that infants frequently gain in weight following the addition of yeast to the diet, apparently irrespective of its previous vitamin content.

There is a growing tendency to adopt the point of view that we have reached a point where we possess a knowledge of all the elements which go to make up an adequate and complete diet, and, accordingly, that our future task is merely to ascertain the absolute and relative amounts of these constituents required under various conditions. The problem is, however, by no means so simple. There are probably many reactions and interactions which have not been considered. I should like to illustrate this point by the *unexplained rôle which cereal plays in the nutrition of the infant*, a phenomenon which has interested me for some time and well illustrates the complexity of dietary problems. Not infrequently infants receiving milk mixtures which should suffice to bring about growth, fail to gain until cereal is given in addition; the babies are generally over six months of age. In our experience, cereal in the form of farina has proved effective where cod-liver oil, egg yolk, beef drippings, or autolyzed yeast has failed (Chart 3). The diets were in some instances rich in fats or carbohydrates, in some they consisted of breast milk. There would be nothing surprising in the fact that an addition of cereal brought about a gain in these babies were it not for the insignificance of the amounts which were able to accomplish this result. The beneficial result could not be attributed to a simple caloric increase of food, for only two to three grams of the dry cereal were given, representing but a slight addition in calories to the dietary. Hopkins¹⁰ reports observations on rats which probably are of a similar nature. He found that after a certain period rats failed to grow on a milk diet. An addition of ferric ammonium citrate or of hemoglobin failed to bring about growth, but when bread was added to the dietary growth recommenced. Recently Mattill and Conklin¹¹ have reported a failure to bring about continued growth in rats on a

Chart 1. Growth following the addition of small amounts of spinach to the diet.

Chart 2. Growth following the addition of small amounts of spinach to the diet.

Chart 3.—Four cases which reached a stationary phase in weight, and where gains were brought about by small additions of cereal to a diet which was adequate in caloric content. The first three diets were unusually rich in fat-soluble vitamins, and the fourth in water-soluble (autolyzed yeast). In the last case (J. H.), 1 gm. of dried cereal, equivalent to 28 calories of food, were added.

milk diet, but success when flour was added, and therefore came to the conclusion that other foodstuffs, in particular starch, provide a requisite which milk does not possess. Osborne and Mendel¹² were able to raise rats to maturity on a diet of milk powder, starch and lard. There is no adequate explanation for this phenomenon, but in studies on animals and on man a rise in the weight curve which cannot be explained according to our present knowledge should not be regarded as being the result of a lack of established or of undiscovered vitamins.

Another point which has not been sufficiently considered in animal experiments is the importance of the physical texture of the diet; whether the food is given in the form of powder, fluid or paste; whether it is coarse or finely divided. If we are to judge by the recent experiences in infant feeding the physical state of the food is of great importance in deciding its nutritional value. The superior value of dried milk over fluid milk, in many cases, is certainly partly attributable to physical changes brought about by desiccation. That this factor plays a rôle also in the nutrition of our experimental animals was made evident to me some years ago when attempting to feed guinea pigs small amounts of cod-liver oil,

All attempts to make them tolerate even a few drops of this oil met with failure; they promptly developed malnutrition and died. Rats, on the contrary, tolerate and thrive on far larger amounts of cod-liver oil. The recent experiments of Hart, Halpin and Steenbock¹³ on leg weakness in poultry showing that paper, in a concentration of 10 per cent. of the ration, was effective in preventing the progress of this disease when added to a synthetic ration has, no doubt, a wider application in animal and human nutrition.

Before leaving this phase of the subject, I should like to refer briefly to an aspect which is well known to the children's specialist and to other clinicians, but is rarely considered by the laboratory investigator of nutrition. I refer to the opposite of disorders due to deficiency, to disorders resulting from an excess, from an oversupply of one or more dietary factors. It seems quite possible that experiments, which, under the prevailing point of view, are judged solely by the criterion of an adequacy of the various food elements, may be more correctly interpreted as due in part to an oversupply of some factor. For instance, we all know that infantile rickets frequently occurs among overfed babies. In experiments on rickets it is entirely inconsequential in regard to the absorption or retention of the essential inorganic salts how great the fat or the protein content of the various diets may be, and, furthermore, in what form these organic constituents are fed? Experiments on rats, which I shall discuss elsewhere, would seem to show that increased protein plays a rôle in this connection. In other words that an excess of some food constituent may lead to a result similar to that brought about by a deficiency.

It is only recently that we have come to appreciate the dominant rôle of latent phases of malnutrition, to realize that we have to deal mainly with disorders of nutrition and not with nutritional disorders. Rickets, scurvy, beriberi, and similar nutritional disturbances of gradual development and slow onset, occur far more frequently in their latent undeveloped forms, than in the dress which we have been accustomed to clothe them. The very fact that scurvy takes months to develop before reaching a stage where it can be recognized, indicates that the number of larval, unrecognizable cases must far outnumber those which can definitely be diagnosed. The same is true of rickets. This realization indicates a marked advance in our conception of the nutritional disorders and will, undoubtedly, change current viewpoints in many respects. When we shall have devised methods to perceive those invisible parts of the spectra of pathological conditions, we shall undoubtedly find them far more prevalent. We may thus be led to the conclusion that their

relative incidence and their geographic and sociologic distribution is different from what we have been wont to believe, having merely the frank and full-blown pictures in mind. Indeed, we are already faced with the difficulty which will increase as time and knowledge advances, of deciding what phenomena justify a diagnosis of certain well-established nutritional disorders. I believe I reflect the opinion of many workers in this field, in stating that there is an increasing uncertainty in this regard, both among clinicians and laboratory investigators. What is to be regarded as scurvy, rickets, beriberi, pellagra, etc., and what is not? As a matter of fact, we all realize that normal nutrition imperceptibly merges into abnormal nutrition. Today we are far from being able to detect nutritional derangements at their earliest beginnings—they have progressed to a marked degree before we finally recognize them and dub them with a definite name such as "rickets" or "scurvy." We constantly have to shift our outposts toward the realm of the normal—arbitrary outposts designating a fictitious boundary between the normal and pathological. It is evident that this trend is leading us unconsciously and little by little away from a consideration of what we now term disease. It is also leading us from curative medicine into the domain of preventive medicine. At present preventive medicine has not advanced sufficiently far to concern itself merely with the preservation of normal physiologic conditions, but includes a large number of mild and latent forms of disturbances.

Those of you who have been following the experimental work in this field will have noticed numerous altered viewpoints which have become increasingly evident during the past few years. It may be well to refer to these newer aspects as, in a measure, they are applicable to human nutrition. Only a few years ago it was considered sufficient to ascertain the effect of a diet for a period of weeks or of months. Today, largely as the result of the investigations of McCollum and of Osborne and Mendel, we know that to regard a diet as completely adequate the observational period must extend at least to the stage of maturity—the animals must grow at a normal rate, must be able to reproduce at frequent intervals, and successfully to suckle their young. More than one generation may have to be followed as a deficiency becomes apparent at times only in future generations. The necessity and wisdom of a survey of a larger span of life was clearly demonstrated in the case of the peoples of the Central Empires during the war. Had the war lasted but two or three years the effect of the inadequate ration would not have been apparent; it required three or more years of a diet, which was insufficient in numerous

particulars (adequate protein, vitamins, phosphates), to bring about unmistakable signs of malnutrition. Furthermore, it is interesting to speculate as to the future course of the growth and development of these children. Will the new generation be of a stature smaller than the present population, or will a belated adequate ration bring about an increased increment of growth? Will this increase come about at once, or will it be deferred until the added growth impetus of maturity?

Not only have we constituted a longer span of life, as the nutritional unit, but we demand special recognition of the various life cycles. The period of active growth is considered a definite entity. It has been found necessary to make still finer distinctions; for example, rickets experiments performed on rats, weighing 30 to 40 g., are recognized as not comparable to those undertaken in rats a fortnight older, weighing 60 to 70 grams. These differences are not merely quantitative to be calculated according to variations in body weight, but are distinctive for the particular period of life; so that an animal during its period of active growth is almost as distinct from the adult animal as if it belonged to a different species. It possesses differences in susceptibility and immunity to the nutritional disorders.

The main factors determining the nutrition of the body are *diet and environment and infection*. This is the triad, which, working hand in hand, or at cross purposes, brings about a physiologic or a pathologic state. It is impossible to give these three factors their relative values, as this varies according to circumstances. Studies of the deficiency diseases have served to illustrate in a manner, more convincing than heretofore, the intimate relationship and interrelationship of nutrition to infection, and have led to our attributing increased significance to nutrition in this regard. Indeed, the chief clinical importance of disorders of nutrition in times of peace and plenty is their effect of so altering the tissues as to render them more susceptible to the invasion of bacteria or toxic products. Clinically it is by no means easy to determine the respective rôle of infection and of nutrition when confronted with disease. Either can result in secondary involvement by the other. There is in my opinion no more common error in considering nutritional disorders in infants, and in judging the merits and demerits of particular foods or food preparations, than attributing failure to the diet where it has been occasioned by mild infection. This is due largely to the conception that infection must be accompanied by a rise of temperature. That this is not so may be illustrated by instances of the mild infectious diseases such as chicken-pox, where a cessation of gain in weight may occur in infants

without any rise of temperature. It is evident also following vaccination, where a stationary weight may precede by a day or two the febrile reaction of vaccinia. This interrelationship of infection and nutrition was exemplified in 1913, when, as the result of a diet of pasteurized milk, latent scurvy developed among a group of infants under my care. This scorbatic taint was followed by a widespread grip infection, with hemorrhagic skin manifestations, which disappeared only in part on the administration of orange juice. For some years it was difficult to know how to interpret this peculiar clinical picture, whether to regard the epidemic as due to scurvy, or to infection. As the result of subsequent experience I realized some years later that it had been due to both causes—the result of a primary nutritional disturbance and a secondary bacterial invasion. It is probable that the overt and classical signs of scurvy—those which are described in the textbook—for example, the hemorrhages of the gums, are not always purely scorbatic or nutritional, but the result of the secondary infection which comes about, sooner or later, in conjunction with this disorder.

The third factor which markedly affects nutrition is environment, which includes the air we breathe, atmospheric conditions, our shelter, clothing, and many other apparently trivial factors connected with our daily life. Here is a field which lies almost untouched, and which, undoubtedly, will prove most fertile. It is one which has been ignored in a consideration of many questions of nutrition. For example, the diets of peoples living in various countries, under divergent climatic conditions, are frequently compared without considering for a moment the possible influence of environment. It is not permissible to compare the dietaries of the children of New York, London, Edinburgh, Dublin, etc., and to interpret their comparative nutrition as if they were all living in the same city. The very fact that the infant mortality—perhaps the most delicate indicator of environmental conditions—of London has been low for many years, in spite of a wretched milk supply and inadequate educational propaganda, indicates the rôle of non-dietetic influences. The effect of environment on plants is well known and may be illustrated by an interesting experiment carried out by the United States Department of Agriculture some years ago. The growth of a certain strain of wheat which grew particularly well in Kansas was tested in California. To this end carloads of the Kansas soil were transported to California for sowing of the seed. In spite of the fact, however, that soil and seed were the same, the yield in California could not be made to equal that of Kansas. There is a

real and growing danger of forgetting these environmental factors in gathering statistics of the geographic distribution of disorders of nutrition, such as rickets, caries of the teeth, etc. Still greater care must be exercised in interpreting the influence of diet on races which lived centuries or thousands of years ago. To draw inferences as to the effect of diet from the condition of the bones of the teeth of the Egyptians, as has been done, is to leave out of consideration differences in dress, in housing, in habits, and perhaps changes in climate, which may well have had their effect on the nutrition of the tissues.

One of the most important factors included under the broad term of environment is the solar rays—light. The peculiar beneficent effect of light was appreciated in far distant ages and led to the worship of the sun, a cult by no means to be belittled when compared with the present-day cult of patent medicines. Hippocrates and Herodotus praised the healing virtues of the sun, and the Romans took sun baths on the flat roofs of their houses. Antyllus, who lived 300 years after Christ, minutely described the indications for the sun bath with and without anointing the body. During the Middle Ages the knowledge of the curative value of the sun seems to have been forgotten. About 50 years ago sun treatment was with difficulty introduced for the cure of tuberculosis and has been carried out with signal success by Rollier in Switzerland. It is strange that the value and need of the sun's rays have not been more fully appreciated when we consider that it has been generally acknowledged by all physiologists that the solar rays are necessary for the proper growth and nutrition of green plants. On the part of physicians this lack of confidence probably is associated with a corresponding overconfidence in pharmacologic preparations, and has been intensified by the fact that heliotherapy has been practised largely by those whom the state did not license to employ accepted methods of therapy. That the physiologists should not have directed the attention of physicians to the potency of this measure shows a lack of appreciation also on their part of the value or the necessity for the animal organism of the sun's rays. From a physiologic viewpoint it would seem that this function of the skin to absorb the effective rays of the sun is comparable to that of the intestine in relation to the constituents of the food—a comparison perhaps the more permissible in view of the similar embryological origin of the integument and the lining of the intestinal tract. Today we know by means of subjective and objective clinical examinations, as well as by animal experimentation, that the sun's rays are able to prevent or to cure rickets; that, indeed, this form of therapy may be regarded

as a specific for this disorder. In my lecture of tomorrow I shall discuss the subject more fully as to the rays which exert this remarkable effect, the influence of pigmentation, the sun's action on the chemical constitution of the blood, etc. It would seem that the action of the sun's rays will have to be taken into account in metabolism studies on animals and on man which concern themselves with the body exchanges of the inorganic salts. From the general standpoint of animal nutrition must we not qualify the usual statement that adequate protein, inorganic salts, the vitamins, water, etc., suffice for nutrition of the animal body, by adding that sunlight must also be provided? This holds true at least for the young, rapidly growing animal.

Before leaving this interesting subject of the effect of solar rays on animal nutrition I should like to mention a clinical observation which suggests that certain constituents of the food may influence the effect of the radiations. A few years ago Myers and P¹⁴ showed that if an infant receives a moderate amount of a food rich in carotin pigment—for example, carrots or spinach—it frequently will develop carotinemia. This condition is quite innocuous and is characterized by carotin in the blood and a discoloration of the skin resembling mild jaundice. Infants having carotinemia are peculiarly susceptible to the sun's rays, the skin having been to a certain degree sensitized, so that the face becomes rough and irritated when exposed to the sun. This condition recalls, in a minor degree, the susceptibility of the skin of rabbits to which eosin has been given. It suggests that other foods or that drugs may act in conjunction with the solar rays.

Nutrition is embracing a broader scope, and its studies, both in the laboratory and in the clinic, and in the world at large, will more and more include a consideration of environment. The effect of atmosphere both out of doors and indoors will have to be carefully studied, and may be found to include factors hardly considered at the present time. Such studies have just begun and can be seriously attempted only when we are able to control some of the factors which comprise climate. This will be no mean task. In closing this consideration of the rôle of environment on nutrition the effect of season must be considered. It is well established that season affects the growth of animals and that children grow more rapidly during certain seasons than during others. The reason for this is not known. Very few studies of the effect of season have been attempted in the laboratory. One of the earliest and most interesting was that of Reid Hunt, which showed that guinea pigs are decidedly more resistant to acetomitrile poisoning

in the spring and summer than in the winter, and that this is probably associated with some seasonal variation in metabolism. Those who have carried out nutritional studies for a series of years must feel that there is possibly a seasonal factor which accounts for certain variations in results occurring under apparently identical conditions. The intimate and clear relationship of season to disorders, such as tetany and rickets—quite apart from its influence on the various infectious diseases—well demonstrates the dominant note which climate may exert in our nutritional state. The three main factors in nutrition—diet, infection and environment—probably are so inextricably bound together that it will be impossible to appraise the rôle of each in the disorders of metabolism in which they are concerned.

SKIN IRRITANTS: EXTERNAL AND INTERNAL*

By C. GUY LANE, M.D., BOSTON.

Assistant Dermatologist, Massachusetts General Hospital.

[From the Dermatological Clinic, Massachusetts General Hospital, Boston, Mass.]

THIS paper deals, first, with certain irritated conditions of the skin definitely resulting from contact with various substances, that is, dermatoses of external origin; and, secondly, with certain eruptions on the skin which are of internal origin, that is, from the taking in of certain substances, or because of the formation of certain substances in the body. It does not include the infectious conditions, either bacterial or parasitic.

Both of these subjects are fundamentally connected with the subject of idiosyncrasy. Idiosyncrasy is defined as an abnormal body response to a certain substance. It is an individual susceptibility, a natural or an acquired sensitiveness of the skin to some particular reagent. These two groups of cases are to be explained on the grounds of an individual sus-

* Read before the meeting of the Middlesex East District of the Massachusetts Medical Society, March 15, 1922.

ceptibility of the patient's skin to a particular substance. They are evidences of an unusual response on the part of the skin to substances which may cause no reaction by an average individual. I realize that this explanation does not give a scientific answer for the cause of these conditions, but it is as good an explanation as any that can be given at the present time. It is theoretically possible that for any given chemical there may be an individual who is susceptible to this agent, and if the list of substances causing such conditions is considered the theory seems almost a reality.

GROUP I. THOSE FROM EXTERNAL SOURCES.

This first group of cases, those from external sources, includes the very large number under the diagnosis of dermatitis and dermatitis venenata, the common garden variety of skin eruptions which we have all seen in practice. Let me further classify these cases under the following headings: (1) Those from plants, etc.; (2) from medicinal applications; (3) from occupation; (4) from an intent to deceive; (5) from accidental contact.

Class 1. Plants.—The type eruption of the first class, those from plants, is usually thought of in connection with poison ivy, varying from erythema to the formation of vesicles and bullæ, with marked itching and burning, etc.; and later with scaling, perhaps becoming much oozematized. One is apt to think of dermatitis venenata as including only ivy as a cause, and to forget there are other substances causing similar eruptions. I have recently reviewed at the Massachusetts General Out-Patient Department some 600 records in which there was a diagnosis of dermatitis or dermatitis venenata. There were only about 10 per cent. of these cases whose history included an exposure to woods or ivy. I had thought that the percentage would be higher. These cases are familiar to all of you.

I want to call attention to one member of this group which is becoming a more frequent cause of such a dermatitis. I refer to the primrose, and especially to the one to which the name *primula obconica* is given.

In this connection, I recall especially a woman of 42 who was referred to me in the X-ray Department for treatment of an eruption on her hands. For several months she had had a patchy, erythematous eruption on hands and face, with occasional tiny vesicles and linear lesions which attracted my attention. Inquiry developed the fact that she possessed a primrose, and coincident with throwing away the plant the eruption faded away. It is needless to say that no x-ray treatment was given.

In the treatment of these cases the majority will clear up with the use of the familiar whitewash of carbolic acid, zinc oxid and lime

water. Strickler¹ has treated a series of ivy cases by the subcutaneous injection of a toxin developed from the plant, and marked relief has been obtained in his cases much more quickly than with the ordinary treatment. This toxin, however, is not yet on the market for general use. Schamberg² has called attention to the use of tincture of rhus given by mouth, not only in the treatment of, but also as a means of prevention of poison ivy dermatitis.

Class 2. Medicinal Applications.—In these same 600 cases of which I have spoken there were many with no cause given, but it was rather striking to find so many cases in the second class, that is, the eruptions following the application of medicinal agents. There were 20 per cent., or one in five, who had a history of applying some ointment, liniment, iodine, etc., to the body surface, with the resulting development of a dermatitis. I realized that there were many patients in this group, but did not imagine that it was quite so large. This irritation has usually resulted because the individual has taken it upon himself to prescribe for his own condition. A certain number have received medicines from the druggist, local physician, and the Out-Patient Department.

We are all seeing such cases continually, and it seems to me that the moral is to be careful in the treatment of acute skin conditions to use soothing treatment, and to use extreme care in the prescription of the stronger drugs and applications. The list of substances is a long one, perhaps the most common ones being iodine, sulphonalphthol, sulphur, mercury ointment, liniments and patent medicines. The story in these cases is usually clear, and the treatment is to forbid further application, and the use of a wash similar to the whitewash before mentioned.

Among these cases resulting from too strong treatment I want to say just a word about scabies. The number of individuals infected with scabies has shown a marked increase in the past two years. There are many more individuals being treated and there are many who think they have scabies, and there is a much more common use of sulphur. It is a fact that 41½ per cent. of these 600 cases, or almost 25 per cent. of those from external sources, had an irritation probably due to the use of sulphur in some form or other. This bears out, in a way, the experience which I had in the army with scabies, where I saw many cases of sulphur dermatitis from the use of sulphur ointment, especially by the boys themselves over a considerable period of time. Sulphur dermatitis is an obstinate condition. It is often as bad as the original scabies. It further complicates the picture and often makes it difficult

to determine whether the scabies is cured. It is often necessary to apply a soothing lotion or ointment to quiet down the dermatitis before the scabies can be treated.

Class 3. Occupation.—Among these 600 cases there were 11 per cent, which were industrial in origin, or probably industrial. It is often difficult to decide absolutely in these cases, but I have included only those in which there was a strong possibility. There are many different causes among these cases. Perhaps the greatest number of patients were housewives, or individuals doing housework. We are apt to forget, I think, that housework, with its soap and water, polishes, cleaners, etc., may be the cause of much disability and annoyance, to say nothing of actual suffering in many cases.

In the shoe factories and other factories, the mills, stores, tanneries, machine shops, etc., many and varied chemicals are used; and with closer attention centered on this subject, with the development of industrial hygiene and factory work, many more cases will be found. There is often need of real detective work in searching for the offending substance, but the only solution is the elimination of the substance causing the disability. That is the proper treatment fundamentally. The majority of the acute cases will then clear up fairly readily with a soothing lotion and mild ointment, such as Lassar's paste, or zinc oxid ointment.

I have been much interested in the preventive work which has been done in two industries, namely, among printers and among vulcanizers. Among printers,³ certain of the pressmen develop an eruption on forearms and hands from contact with the inks, with benzine, and from the various methods used in removing inks from the hands. A good deal of experimental work was done on these individuals and it was found that the application of an oily mixture composed of lanolin and oil before going into the pressroom, and the use of a mixture of sawdust and a liquid soap for cleansing purposes, was sufficient to prevent the greater part of these eruptions.

In some of the rubber factories certain of the vulcanizers who were using hexamethylenamine in their work developed an eruption on hands and forearms. Without going into an explanation of the research work involved, I will state that the chemists of the Firestone Rubber Company⁴ found that the immersion of the exposed parts in an alkaline solution, such as a saturated sodium bicarbonate solution, before going to work, was sufficient to prevent this eruption from appearing in those individuals who were sensitive. Examples of cases in this group are numerous.

I recall the case of a photographer's assistant with a very marked oozing, red and crusted skin on hands, forearms and neck, probably

from contact with the chemicals used in developing.

I also recall the case of a machinist working without any sleeves, and with overalls practically saturated with oil. This man showed a very marked folliculitis on both arms and thighs, due to the action of the oil.

Cases in our own profession, among nurses and physicians, from the use of antiseptic solutions of one kind or another, are familiar to all of us. Among dentists are found individuals who are susceptible to novocain, with the result that they have at times much disability from irritated conditions upon the hands.

Class 4. Intent to Deceive.—In the fourth class I wish to mention those cases of dermatitis which are artificially produced by the individual with the intent to deceive. These eruptions occur among malingerers, neurotics, individuals who desire sympathy, or who desire to be free from certain work, or desire to gain admission to hospitals, etc. There are many agents, physical and chemical, which are used to produce these eruptions. They usually present weird combinations of dermatological lesions, and the very strangeness of these combinations often leads to the discovery of their cause. These patients are oftentimes very hard to handle and much patience and tact are necessary in dealing with them.

Class 5. Accidental Contact.—Finally, in the fifth class of these eruptions I am including those cases from accidental contact—the unusual, infrequent cases which do not come in any of the other groups. These cases are often a real puzzle picture and there is need of more of the same detective work which I have mentioned before. The list of substances in this group is very large. It is stated that one physician has a series of 500 cases in each of which a different substance has been the exciting cause. Some idea of the variety can be obtained from the following partial list occurring in these 600 cases: Match box, fur, citronella, wool, hair dye, hair tonic, etc. The following cases will give an idea of this group:

A man, 35 years old, presented himself with a red, infiltrated, rather sharply defined patch on the anterior surface of the right thigh, giving a history of three different similar attacks appearing in much the same area, with intervals of clear skin between attacks. The source of the trouble was finally located in the match box which this patient habitually carried in the right-hand trousers pocket.

A woman, 32, was seen recently with a bright red, papulo-vesicular itching and burning eruption on neck, face and hands. The eruption was sharply circumscribed at its lower border on her chest, coinciding with the upper edge of her dress. She had recently bought a new fur coat; she had worn it several times for

short periods; and on the day of the appearance of this eruption she had worn it to Worcester in the cars, a matter of two hours. Itching and burning had started on that same evening. This dermatitis was undoubtedly due to the dye used in the fur coat. The eruption cleared rapidly in three or four days and since that time she has had two slight attacks, but has finally come to the conclusion that it is necessary to give up the fur coat.

A woman, 42, giving a story of having her hair dyed occasionally, appears with a red, oozing, crusted eruption on forehead, ears and neck, with patches scattered through the scalp; a few small areas on fingers; with a story of having hair dyed two days previously. This case is undoubtedly due to the dye used on the hair.

I am also including in this group some cases which recent research work has demonstrated should be included in this category. I refer to the babies having a dermatitis in the diaper area, this dermatitis usually being associated with an ammoniacal odor. Cooke⁵ of St. Louis has demonstrated that this effect is due to a Gram-positive bacillus in the stool which has the property of fermenting urea and producing ammonia, with the resultant irritation on the buttocks. Without going into the detail of the experimental work, Cooke found that impregnating the diapers on the last washing with some antiseptic, such as mercury bichlorid, 1:5,000, or boric acid, 1:20, and drying the diapers, enough antiseptic remained in the cloth to inhibit the action of the bacillus and cause disappearance of the odor and the consequent clearing of the eruption. This is a comparatively recent piece of work and, I believe, will help us in giving relief to many of the babies who have bothered us so much in the past.

In this series of 600 cases there is one other condition which is confused with dermatitis venenata. I refer to the parasitic group. We are finding that many of the vesicular eruptions on the hands and between the fingers, especially where the areas tend to be sharply limited and to affect the web of the fingers, are associated with the fungus found in the ringworm of the crotch—*tinea cruris*—commonly known as "red flap." It affects the feet and hands and crotch usually, or any one of these, and on the hands may suggest the picture of dermatitis venenata or eczema. I found that in 2 per cent. there was a question of dermatitis venenata and parasitic infection—epidermophytosis. This latter infection is often a very obstinate one and requires vigorous treatment. We often use a combination of acid salicylic, 2; acid benzoic, 4; in adipis benzoat, 30; or 1:5,000, a potassium permanganate solution; or elchysarolin, 2 per cent., in these cases, but many are very resistant to treatment.

GROUP II. THOSE FROM INTERNAL SOURCES.

In speaking of the second group of dermatoses—those of internal origin—there is without question the same relation between these cases and individual susceptibility. The most frequent example of this condition is found in the condition commonly known as hives—urticaria. This is usually associated with the ingestion of some one particular type of food, or a certain group of foods. We see the same condition following the administration of serum not infrequently.

In the acute type, diagnosis is usually easy, and it is often fairly easy to detect the offending article and caution the individual in regard to its use. These cases usually clear up with the use of a saline, restriction of diet, and the use of a soothing lotion to relieve the itching. As a routine, we are apt to use calcium lactate in most of these cases. The acute type often responds to a hypodermic injection of adrenalin, at least temporarily, and there is, at times, very marked relief following its use. In some of the others, emetine hydrochloride is used, but I am not as familiar with the use of this drug.

The chronic persistent types, particularly the chronic papular urticarias in children, are often a very great test of one's patience and of one's knowledge of therapeutics. Hazen has found that a certain number—in fact, about one-third in his series—had a positive Wassermann, and that in these the symptoms disappeared coincident with antisyphilitic treatment. He further found that a large number of them were undoubtedly associated with focal infections, such as tonsils, teeth, etc. It is possible that in a number of others some one particular food is at fault, and further attempts to detect this food element, if possible, should be made. In some of these cases the French are using more and more, according to the literature, powdered peptone, taken before meals, to aid in the desensitization process. In certain other cases the injection of a foreign protein, such as a typhoid vaccine, seems to act as a desensitizing agent.

In giant urticaria, often called angioneurotic edema, the condition may at times become serious because of the tremendous swelling about the face and neck, sometimes involving the epiglottis. At such times it is well to have adrenalin at hand for use in the event of an acute crisis.

I want to mention, in passing, toxic erythema, and the serum reactions to which I have just referred. The former are more frequently seen in children, and in many of these it is a matter of differential diagnosis from scarlet fever. In the latter are seen the cases which are examples of real anaphylaxis.

There are certain other cases classed under the diagnosis of eczema or pruritus, or under the chronic urticaria of which I have spoken before, which I believe can be included in this group of dermatoses. I refer to those cases caused by the absorption of some food element which affects only a comparatively few individuals susceptible to that particular food element. It is now being found that a number of these cases are a reaction on the part of the skin to some one particular food element. This condition is seen most often in children. For example, in a recent series of eczema in breast-fed babies, it was found that there were 40 per cent of apparent cures, and 20 per cent showed improvement following the elimination of food in the mothers' diet to which the babies were susceptible.

These cases of sensitization are most frequently found in connection with egg albumen, but cases are on record of sensitization to other substances, such as pork, potatoes, carrots, tomatoes, etc. Occasionally there has been reported a real collapse, that is, a real anaphylactic reaction caused by the use of egg albumen.

A middle-aged woman for six months had rather generalized itching, many excoriations, and areas where the skin was much eozematized. She had noted an increase of symptoms after eating tomato, and skin tests on her arm showed a reaction to tomato. She has been well since omitting tomatoes from her diet.

There is also the case of a man of 43 who had had pruritus ani for three years, showing much eozematization from scratching. He was found to give a reaction to pork, and his condition cleared with the removal of this article from his diet.

I have been speaking of the skin tests. These occasionally give a valuable clue, but I feel that the value of this test, like many others, is overestimated. It may, however, give valuable information. Like the Wassermann or Widal test, a negative reaction means nothing. A single positive test standing out among a group of negative ones may mean a great deal. The treatment of these cases, of course, consists in a search for the offending substance and its elimination from the diet. So far as I know there is no method of desensitization in these cases.

Let me also mention the pruritus and eczema occurring in diabetes. This is occasionally the first symptom of a diabetic condition, and some work has been done showing a high blood sugar, or a low sugar tolerance in certain of these cases, especially in the pruritus and eczema of the perineal region.

The last group of cases to which I wish to call your attention includes certain drug eruptions. We see rather commonly eruptions fol-

lowing the ingestion of certain drugs, perhaps more commonly after the use of bromide and iodide, but it is only of two or three of the newer drugs of which I wish to speak now.

Luminal is one of our new hypnotics to take the place of bromide as a sedative. Recently at the Massachusetts General Hospital we have had four cases of an eruption associated with the use of luminal, which has served to impress this fact upon our minds. This eruption has been a widely scattered, bright red, macular eruption, the individual elements being small, irregularly shaped macules.

Pherobothalein² is another drug of which an increasing number of cases are being reported. I have always thought that this drug was not absorbed but had some mechanical action upon the mucous membrane. There are, however, certain individuals who are susceptible to it. The eruption in these cases shows widely scattered, irregular, bright red, or even purplish plaques, which show some infiltration. The pigmentation often persists for a considerable period of time afterwards.

Arsphenamin and neoarsphenamin are two other drugs by which an eruption may be caused, this eruption consisting perhaps of a few red macules on forearms and legs, or of an exfoliative dermatitis in some cases.

In concluding I want to give just a word of caution in regard to other forms of arsenic. It is because I have seen rather recently two or three cases of skin change due to the ingestion of arsenic over a long period. There appears the arsenical keratosis of palms and soles, which is seen most commonly. There occasionally appears the generalized arsenical pigmentation. Furthermore, there appear the small, scattered, seborrheic, scaly areas which are not unlike the keratotic areas in elderly individuals which later develop into epithelioma. I feel that these words are not uncalled for, because of the fact that arsenic is prescribed so often for all sorts and kinds of skin conditions.

Finally, I wish to cite, as an example of both of these groups of cases of which I have been speaking, a case of rather extreme sensitization to various factors.

It concerns a man of 24, who was a painter by trade before entering the army. In the army he had a scabies for several months, and apparently had considerable treatment. He appeared at the Out-Patient Department with rather a marked eruption of scabies and was given our usual treatment and directions. Three days later he returned with a very marked dermatitis venenata from the application of the ointment. At the end of a week he returned and his scabies had gradually faded out, but certain areas suggested a macular eruption of syphilis. Further examination showed a primary and mucous patches in his

mouth, so that a diagnosis of syphilis was made. He had one dose of arsenphenamin on that day. Two days later he was admitted to the hospital with a generalized exfoliative dermatitis, undoubtedly due to the arsenphenamin. This cleared gradually and he was discharged from the hospital. He attempted to resume work as a painter, but after each of five attempts an erythematous and finely papular eruption appeared on hands, face and neck.

This is one of the most marked cases of individual susceptibility which I have seen and illustrates very well the subject under discussion this evening.

TREATMENT OF FRACTURE INVOLVING LOWER END OF RADIUS WITH ANTERIOR AND POSTERIOR WOODEN SPLINTS.

By T. K. RICHARDS, M.D., BOSTON.

Most of the functionally poor results following fractures involving the lower end of the radius are due to two causes: first, improper reduction; second, too long fixation. It is not the purpose of this paper to discuss the former but to outline a plan of treatment using an-

terior and posterior wooden splints which gives good results functionally.

The first essential in treatment of these fractures is to break up the impaction. Then the fragments must be immobilized. To do this with as little immobilization as possible to the nearby joints—the carpals, metacarpals and phalanges—is desirable. To accomplish this the following points about cutting the splints are all important (Fig. 1).

Place the good arm on a piece of splint wood with the hand ulnar flexed and mark the following seven points:

1. The radial side $1\frac{1}{2}$ inches below the internal condyle of the humerus.
2. The ulnar side $1\frac{1}{2}$ inches below the internal condyle of the humerus.
3. The radial side outside the first metacarpal-carpal joint.
4. The radial side inside the first metacarpal-phalangeal joint (between the thumb and index finger).
5. The radial side just proximal to the second metacarpal-phalangeal joint (this point is well down in the palm of the hand and not near the base of the fingers).
6. The ulnar side just proximal to the fifth metacarpal-phalangeal (here again the point is well toward the heel of the hand).
7. The ulnar side just distal to the styloid of the ulna (this point should be the width of the bones, not the width of the arm, from No. 3).

The radial side of the arm is straight so the splint need not be cut along this edge. Joining No. 1 to No. 2 gives the length of the splint; No. 3 to No. 4 cut out gives a hole for the thumb; No. 5 to No. 6 gives the distal end of the splint across the palm; No. 6 to No. 7 forms the ulnar side of the hand, and No. 7 to No. 2 forms the ulnar edge. When joining No. 4 to No. 5 it is best to make this line parallel to No. 6 to No. 7, as it makes the application of the adhesive easier. (For location of the seven points see Fig. 2.)

FIG. 1.—1, Straight board used as a posterior splint. 2, The usual posterior splint. 3, The anterior splint. 4, The cut-down anterior splint.

FIG. 2.—The anterior splint applied. The numbers indicate the points to be marked when cutting out the splint. Note that the hand is in ulnar flexion, i.e., that the portion of the splint in the palm is well away from the metacarpal-phalangeal joints.

The finished splint then fits the bones of the forearm. If it has been made to fit the arm it is possible for the bones to move within the splints (c, f, Fig. 3).

FIG. 3.—Showing the difference in the width of the splints that fit the arm (A) and those that fit the bones (B). It will be readily seen that in A the bones can move within the splints while this is not so in B, where small splints that fit the bones and not the arm are used.

The hand is held in ulnar flexion, which tends to exert traction on the lower fragment of the radius and thus prevents shortening of the radius. Full motion of all the finger and thumb joints is secured, which will keep the tendons from "freezing." (Fig 4).

FIG. 4.—The anterior and posterior splints applied. Note that full motion of all finger and thumb joints is secured.

The posterior splint is the same as the anterior except that the hole for the thumb is unnecessary (another perfectly satisfactory posterior splint is a straight piece of splint wood the length of the anterior splint and the width of the forearm bones).

Both splints are now padded—on the side next to the skin—with eight to ten layers of tightly folded sheet wadding (in large forearm it is necessary to insert an extra pad on the anterior surface near the point of fracture to make the splint fit well) and are held in place by three pieces of adhesive,—two, two inches wide and long enough to encircle the splints and the arm. One of these is placed at the proximal end of the splints and the other at the site of the fracture. The third piece of adhesive, one-half inch in width, encircles the splints across palm between the thumb and index finger. When this is applied make sure that the hand is in extreme ulnar flexion.

With the splints in position the patient should be able to move the elbow-joint, all fingers and thumb freely. If the fingers cannot be manipulated so that the tip of each finger can be touched to the thumb the splints do not fit properly, and steps must be taken to make

such motions possible. The commonest cause preventing these motions is that the portion of the anterior splint in the palm of the hand is too long, i.e., it extends beyond the metacarpal phalangeal joints. A second cause is that the whole anterior splint is placed too far distally.

The next point is, how long should the splints be left on? Clinically, union in fractures in lower end of radius begins very early, as is readily demonstrated by the difficulty with which a fracture of the lower end of the radius can be reduced at the end of 48 hours. This is due to impaction of fragments plus inflammatory exudate. Experimentally, it has been shown that in fractures of spongy bone (of which the radius is one) at the end of 48 hours the process of repair—exudate at the site of fracture and organization of the exudate—has well started. Therefore allow twenty-four hours more and the fragments are "stuck" tight enough to allow still more motion to the joints of the hand. Hence at the end of three days remove the posterior splint.

Remembering that the lower end of the radius is the portion which must be held, at the end of one week shorten the anterior splint by cutting two to three inches from the upper end and re-apply.

FIG. 5.—The cut-down anterior splint applied.

At the end of ten days cut the anterior splint down to the width of the radius (Fig. 5). The splint left extends from about the lower third of radius to the middle of the palm with a hole for the thumb. This is held by two strips of adhesive—one at each end. Solid union is secured in twenty-one days. Therefore take off all splints at the end of three weeks.

With the first application of both splints the patient is encouraged to move the fingers constantly—this is extremely important as it will do much to prevent the stiffening of all the joints in the hand. A sling is usually not necessary beyond the first three days except that on the street it acts as a sign, "Don't bump into me, please," and without one the patient will use the hand a great deal more.

In elderly individuals and in patients with arthritic tendencies early massage and passive motion, in addition to active motion of fingers, are all important. When a first-class masseur

is available daily massage and passive motion should begin on the tenth day. Following each treatment the cut-down anterior splint is re-applied. At the end of three weeks the patient is told to use his hand normally, augmenting this with massage. At this time the patient will feel more confident if given a supporting bandage.

CONCLUSIONS.

To secure the maximum good results functionally in fractures involving the lower end of the radius treated by immobilization with anterior and posterior wooden splints the following points are important:

1. Break up the impaction.
2. Immobilize with splints that fit the bones and not the arm, *i.e.*, narrow splints.
3. Remove the posterior splint on the third day.
4. Cut down the anterior splint on the tenth day.
5. Remove all splints on the twenty-first day.
6. Be sure of active motion of the fingers at all times.
7. Begin intelligent massage and passive motion on the tenth day.

In a word—"move the joints adjacent to the fractures at the earliest possible moment."

Experience with this method of treatment on the Third Surgical Service (Dr. E. H. Nichols) at the Boston City Hospital, in the Surgical Out-Patient Department and among players on the Harvard football team, has shown that the above method not only maintains the desired continuity of the fractured bones but insures function of the injured arm at an earlier date than any other method.

TWO CASES OF EARLY CARCINOMA OF THE UTERUS TREATED BY VAGINAL PANHYSTERECTOMY.

By LOUIS E. PHANEUF, M.D., F.A.C.S., BOSTON.

Associate Professor of Clinical Gynecology, Tufts College Medical School, Boston.

It is not intended that this paper should offer anything new on the subject in question, but merely to serve as a reminder that the vaginal route may offer the solution of certain problems in gynecological surgery where abdominal section is contraindicated. Both of the cases I wish to report were cases that needed operative interference; one, a borderline case in which the disease was discovered only by examination of curettings from the uterus; the other, an epidermoid carcinoma grafted upon a proclivita of many years' standing. Both cases were declared unsuitable risks for abdominal panhysterectomy by the

medical service of the Carney Hospital; both patients had vaginal panhysterectomies performed and made uneventful recoveries.

CASE 1. Mrs. M. G. S., Age 42, Occupation, nurse. Admitted to the Carney Hospital, November 15, 1921.

Chief Complaint.—Excessive flowing.

Past History.—Measles and pertussis during childhood. Operation for right inguinal hernia in 1914.

Menstrual History.—Onset at 15 years of age; every three weeks; duration ten days; flow considerable in amount; last period October 29, 1921.

Marital History.—Married 15 years; one pregnancy complicated by eclampsia 14 years ago; difficult forceps delivery; stillborn child.

Present Illness.—Since the birth of her child 14 years ago the patient flowed for ten days at intervals of three weeks; the flow was always excessive in amount. She has lost ten pounds in the last year.

Appetite fair. Bowels constipated. Urination negative. Headaches frequent and severe.

Physical Examination.—Negative, except for marked secondary anemia and emaciation.

Vaginal Examination.—Moderate relaxation of the vaginal outlet; no sign of infection of the urethra or the vulvo-vaginal glands; moderate laceration of the cervix with erosion. The uterus is moderately enlarged and in good position; the adnexa are normal and there are no masses or areas of tenderness in the pelvis.

Blood pressure 128/85.

Urine examination negative.

Operation.—November 17, 1921. Gas ether anesthesia.

The ether examination confirmed the previous findings. The uterine cavity measured three inches. The cervix was dilated and the uterine cavity was everted, considerable hyperplastic tissue being obtained. The patient made a good ether recovery and convalesced satisfactorily.

Pathological Report.—Uterine curettings. Marked hypertrophy of endometrium; suggests possibility of transformation into malignant adenoma; would advise careful watching. (Signed) F. B. Mallory, M.D.

Medical Consultation. Dr. John F. Fennessey.—Heart shows a mild myocarditis. The lungs are negative. Would advise a vaginal rather than an abdominal operation.

The above conditions were explained to the patient, who preferred to have a hysterectomy rather than await developments. The vaginal route was chosen because of her poor physical condition.

Operation.—November 29, 1921. Gas ether anesthesia. Vaginal panhysterectomy. Double sigmoido-oophorectomy.

A circular incision was made around the cervix, and the anterior vaginal wall was opened by a longitudinal incision. The bladder was separated from the anterior wall as well as from the uterus, and the vesico-uterine peritonium was opened. The cul-de-sac of Douglas was incised transversely and the peritoneal cavity was entered posteriorly. The parametria and the uterine vessels were ligated with No. 2 chromic catgut and divided. The fundus of the uterus was delivered through the opening in the vesico-uterine peritonium and the infundibulo-pelvic and the round ligaments were ligated with the same material. The uterus and the adnexa were then removed. The parametrial, the round ligament, and the infundibulo-pelvic pedicles were attached to the vaginal cuff and the vaginal incisions were closed with No. 2 chromic catgut interrupted sutures.

The patient made a good ether recovery; there was no elevation of temperature, although the pulse ranged between 130 and 120 for ten days.

Pathological Report.—Uterus (fundus, body, cervix), tubes and ovaries. Mucosa almost entirely removed. No evidence of invasion. (Signed) F. B. Mallory, M.D.

December 14, 1921. *Discharge Examination.*—Vaginal incision well healed. The vaginal vault is suspended high in the pelvis. There are no masses or areas of tenderness.

December 18, 1921. Discharged well.

CASE 2. Mrs. M. B. Age 54. Referred by Dr. John T. Bottomley. Admitted to the Carney Hospital, January 17, 1922.

Chief Complaint.—"Falling of the womb," "Irritating discharge."

Family History.—Father dead; cause unknown. Mother died of pneumonia. One brother died of apoplexy at 24 years of age. No tuberculosis, cancer, diabetes or insanity in the family.

Past History.—Measles, pertussis and chicken pox during childhood. Twenty-five years ago the patient had what she described as "slow fever" for two months; this condition was accompanied by fever and chills. Never sick otherwise, never operated upon.

Menstrual History.—Menstruation was regular up to 14 years ago, at which time she had the menopause.

Marital History.—Married 40 years. Husband living and well. The patient had 14 children; eight are living and well, while six died during childhood. The oldest child is 37 and

the youngest is 16 years old. All deliveries and puerperia were normal.

Present Illness.—The patient has had "falling of the womb" for the last fourteen years; five years ago she noticed considerable irritation about the vulva and cervix. The condition was relieved by local medication. Since May, 1921, the patient has had an irritating brownish discharge, which has gradually increased in amount, and has become more sanguinous in character.

Headaches slight; appetite fair; bowels regular. Urination—Day, 4-5; night, 0.

Physical Examination.—The patient, who is short in stature, weighs 275 pounds. Head shows no abnormalities to external examination. The teeth are all absent. The tongue is clear, protrudes in the median line and shows a slight tremor. The neck is obese but shows no glandular enlargement; the thyroid is normal. The chest is barrel-shaped, the heart and lungs are normal. The abdomen is very obese and flabby, otherwise it is negative. The blood-pressure is S. 155, D. 88. The urine is negative.

Vaginal Examination.—The uterus is prolapsed in the third degree; a large cystocele and rectocele are present; the cervix is markedly hypertrophied and shows a large, raw area with indurated edges; there is no apparent glandular involvement.

Medical Consultation.—Dr. Edward J. Denning.—Patient's general condition makes an extensive abdominal operation inadvisable; she might stand a quick vaginal operation.

Diagnosis.—Uterine procidentia, carcinoma of cervix.

Operation.—Vaginal panhysterectomy, anterior colporrhaphy, perineorrhaphy.

January 19, 1922.—Gas ether anesthesia.

The hypertrophied and ulcerated cervix was brought down by means of two sutures placed in sound tissue. A circular incision was made about the ulcerated area, and the anterior vaginal wall was opened in the median line. The bladder was separated from the mucosa and fascia of the vaginal wall, the utero-vesical ligament was cut and the bladder was separated from the uterus. The cul-de-sac of Douglas was then opened and the parametria and uterine vessels were secured by means of No. 2 chromic catgut sutures. The uterus was delivered through an incision in the utero-vesical peritonium, the infundibulo-pelvic and round ligaments were ligated with the same material and the uterus was removed. There was no glandular involvement in the pelvis as far as could be determined. Because the cystocele was large, the round ligaments were sutured together and interposed between the bladder and the vaginal wall, after the excess of the flaps

had been cut away, and the anterior vaginal wall was closed with interrupted sutures of No. 2 chromic catgut. A high modified Hegar perineorrhaphy was performed for the rectocele.

The patient was on the table fifty-eight minutes; she took ether very badly and oxygen was administered during the entire operation.

The recovery from ether was entirely satisfactory, the convalescence was uneventful, except for a slight amount of urinary incontinence, which the patient overcame in four days. The highest temperature was 100° on the second day after operation and the highest pulse was 104 on the same day.

Discharge Examination. — The perineum is well healed and gives excellent support. The anterior wall is healed and is suspended high in the vault. There are no raw areas in the vagina. The patient was referred to Dr. A. J. Leary for x-ray treatments.

CONCLUSIONS.

Both of these cases needed operative interference but their general condition contraindicated extensive abdominal operations.

The first case was one in which we felt that a hysterectomy offered the patient a better chance than radium therapy. Because of the marked secondary anemia and the patient's poor physical condition the vaginal route was chosen to avoid the shock which frequently follows the abdominal operation.

The second case had an epidermoid carcinoma of the cervix, the result of prolonged irritation of a neglected procidentia. While radium might have healed the ulceration, it would not have removed the cause of irritation, namely, the uterine prolapse. It was thought advisable to remove the uterus and at the same time cure the cystocele and rectocele. This was done in one stage and the patient made an uneventful recovery.

The vaginal operation has distinct advantages in a selected group of cases. It is contraindicated in the presence of pelvic inflammation and where the uterus is of such size that it cannot be easily delivered into the vagina. It is especially adapted to poor surgical risks whose uteri are freely movable and readily delivered through the vaginal canal.

The main objections to vaginal hysterectomy have been hemorrhage, injury to the bladder and the ureters, and prolapse of the vaginal walls. The first two are easily overcome by ligating the vessels before dividing them and by completely separating the bladder from the uterus, following the technic used in doing the interposition operation. Since in doing an abdominal hysterectomy we use the infundibulopelvic, the round ligament and the parametrial pedicles to suspend the vagina, there is no rea-

son why we should have any more prolapse when doing the vaginal operation than in the abdominal one if we attach the same pedicles to the vaginal cuff. In addition, we are able to remove the excess of the flaps of the anterior vaginal walls, and to build a substantial support for the bladder, if necessary. Furthermore, if the perineum is relaxed, it may be quickly repaired without changing the patient's position, and this also adds to the support of the bladder and the rectum.

The convalescence is usually very satisfactory, and since the intestines are not handled during the operation, distention is practically never encountered as a post-operative complication.

Book Reviews.

Collected Papers of the Mayo Clinic, Rochester, Minn. Edited by MRS. M. M. MELLISH, Vol. xiii. Philadelphia and London: W. B. Saunders & Co., 1922.

This very valuable volume covers a wide range of subjects, the list of contributors being men most active in the Mayo Clinic at the present time. The contents are grouped under several headings, such as: Alimentary Tract; Urogenital Organs; Ductless Glands; Blood; Skin and Syphilis; Head, Trunk, and Extremities; Brain, Spinal Cord, and Nerves; Technic, and General.

Under the heading of "General" are several papers on cancer, diabetes in relation to surgery, value of radium in malignancy, an article on the trained nurse, a historical review entitled "In the Time of Henry Jacob Bigelow," and an article entitled, "The Medical Profession and the Public."

There is an index of contributors, a bibliographic index, and an index of subjects. One particularly valuable feature of most of the articles is the bibliography appended after each article.

Illustrations are many and adequate. There are 1318 pages, representing about five hundred separate articles. These articles bring many subjects well up to date and furnish much that is new in the way of experimentation, latest theories in regard to causation of disease, and of surgical technic.

The book is one of the most varied and valuable collections of papers yet issued. Our only criticism would be that many of the articles are perhaps too brief and do not give wide enough synopsis in the concluding remarks.

Internal Secretion and the Ductless Glands.

SWAIN VINCENT. Second Edition. Longmans, Green and Company, 1922.

It is a pleasure to read a good book on the Internal Secretions, particularly at this time, when so many inaccurate, imaginative productions are flooding our bookstores. The second edition of Professor Vincent's book brings it up to date. There is, however, one unfortunate omission: the elimination of references makes its use as a reference book difficult; for on a subject which is changing so rapidly and concerning which there is so much inaccurate material, it is essential for a clear understanding that references be available. There ought to be in the text at least an indication—such as the date of publication after the author's name. This single criticism, however, stands alone in what is otherwise a laudatory review. The method of attack by the anatomical and comparative physiological methods is excellent, and aids markedly in understanding what is known about the functions of the endocrines. And the book has the great advantage of basing conclusions only upon scientific data. There are, consequently, places where it seems incomplete; but this is the fault of our own scientific knowledge rather than of the author's. The book is recommended to those who want to know, without much theorising and with the evidence well described from the scientist's point of view, what has been discovered about the internal secretions.

Skin and Venereal Diseases. The Practical Medicine Series, Vol. vii. Edited by OLIVER S. ORMSBY, M.D., and JAMES HERBERT MITCHELL, M.D. Chicago: The Year Book Publishers, 1921.

The publishers call attention to the fact that "the present volume is one of a series of eight, issued at about monthly intervals, beginning in May, and covering the entire field of medicine and surgery. The series is intended primarily for the general practitioner, but the arrangement in the volumes is such that one interested in a special subject may buy only the part in which he is especially interested."

The seventh volume of the series is devoted to the skin and venereal diseases. In it will be found abstracts from leading articles on the subjects arranged under three main headings, experimental, clinical, and therapeutic.

The articles are abstracted clearly and intelligently. They all have a worth-while story to tell which is well told.

Anyone reading this volume on Skin and Venereal Diseases year by year may rightly feel that he is up with the times. It can be recommended to practitioner and specialist alike. Each will find in it much that is valuable and worth knowing.

Transactions of the American Gynecological Society. Vol. xlv.

In this volume the papers read before the American Gynecological Society for 1921 are grouped. They have all been published in other journals before, and they need no special comment at the present time. The one article that stands out in the group is the one by Dr. Sampson of Albany on "Perforating Hemorrhagic Cyst of the Ovary." It is a remarkably clear, well thought out, original piece of work.

Practical Psycho-Analysis. By H. SOMERVILLE, B.Sc., F.A.C.S., L.R.C.P., M.R.C.S. New York: William Wood & Co., 1922.

This small volume is another treatise on the general principles of psychoanalysis, and it only differs from books of this class in that it discusses almost wholly the clinical aspects of the war neuroses and their underlying mechanism, according to the psychoanalytic viewpoint. In a general way, the practical treatment of the war neuroses has shown the fundamental soundness of psychoanalysis, because it has been demonstrated that the mind of the war neurotic represents a mind which has regressed to an earlier period of childhood. The book is well written, clear, intelligent, and sympathetic. This sympathetic attitude differs from the resistances, prejudices, and emotional discomforts of some writers on the subject, when faced with the truths of this most important of all recent advances in neurological therapeutics.

The book, however, is obscure on several points, such as the introduction of the terms subconscious and co-conscious instead of limiting the discussion to the term unconscious, a procedure which is bound to confuse the beginner. In addition, the example given of eliciting the Oedipus-complex, is too much in the nature of a cross-examination and leading questions, and too little encouragement is given for the spontaneous productions of the subject under analysis. The difficult subject of narcissism is handled very well, except that there is not described with sufficient clearness the important part played by the narcissistic component of sexual hunger, in the production of the anxiety and dread of the war neuroses.

A Psycho-Analytic Study of Psychoses with Endocrines. By DUDLEY WARD FAY, PH.D. Washington: Nervous and Mental Disease Publishing Co., 1922.

This volume is number 33 of the Nervous and Mental Disease Monograph series. It is both psychoanalytic and endocrinological, the object of the study being to discover whether or not there existed any correlation between certain endocrine disorders and certain psychotic syn-

dromes. Twenty-two case histories are given in detail. The results of the study seem to corroborate the final conclusions of Kraepelin (who at one time suspected that there might be some connection between schizophrenia and endocrine disorders), but who finally failed to establish any connection between psychosis and endocrine imbalance, particularly after he had attempted for a long time to influence the course of schizophrenia by the administration of various ductless glandular products.

Most of the cases studied in this monograph were schizophrenics of rather intense grade of severity, too introverted and too far removed from reality to be influenced by psychoanalytic treatment. The effects of gland feeding were only temporary stimulation, although the writer feels, that in incipient schizophrenia, a combination of thyroid stimulation and psychoanalysis might be an excellent method of attack.

Bulletin of the Massachusetts Department of Mental Diseases. Vol. v, No. 1. 1922.

This excellent publication has now reached its fifth volume and the present number is fully up to the standard of its predecessors. The articles comprise a wide scope in general psychiatry, such as neuro-syphilis, social psychiatry and general papers on more technical laboratory studies.

OPEN PNEUMOTHORAX IN ITS RELATION TO THE EXTIRPATION OF TUMORS OF THE RIGHT CHEST WALL.

HEDBLUM, C. A. (*Archives of Surgery*, May, 1922) very thoroughly discusses the question of pneumothorax, the conditions under which it is most liable to occur, its dangers, and its final outcome. He recognizes the disadvantages of having this accident happen in the course of operative work on the chest, but he shows that it may happen under almost all conditions without serious damage. The article furnishes an interesting discussion of this particular subject. [E. H. R.]

THE GENERALIZED TYPE OF OSTEITIS FIBROSA CYSTICA.

MORTON, J. J. (*Archives of Surgery*, May, 1922), gives a brief but thorough description of this disease with a typical case illustrated by many excellent plates, and shows the benefit to the femur from the use of the wedge-shaped osteotomy. He then classifies the types of this disease and gives a chart of the various reported cases. [E. H. R.]

UNDULANT FEVER IN MALTA.

ZAMMIT (*Ann. Trop. Med. and Parasit.*, vol. xvi, p. 11), and STEVENS (*ibid.*, page 11). Discussing the prevention of undulant fever, Zammit points out that this disease was promptly and almost completely eradicated from the British Navy in the Mediterranean as well as from the Garrison at Malta after 1906. This followed the promulgation of orders by which goat's milk was eliminated from the dietary of the Garrison and the use of unboiled milk was forbidden in the Navy.

In spite of efforts of the Sanitary Office to instruct the native civilian population, these people remained sceptical as a rule and failed to follow the advice given, with the result that the incidence of undulant fever among them remains considerable.

Adequate inspection of goats and destruction of all infected animals is therefore recommended as the only feasible method of eradicating the disease from Malta.

Stevens provides data and charts which show in a striking manner the incidence of undulant fever in the Navy, the Garrison and in the civilian population before and after 1906.

"A Parasite Resembling *Plasmodium falciparum* in a Chimpanzee." B. Blacklock and S. Adler (*Ann. Trop. Med. and Parasit.*, vol. xvi, p. 99).

The writers found in the blood of a chimpanzee in Freetown, West Africa, a parasite morphologically indistinguishable from *Plasmodium falciparum*. The parasite appeared to them to be the same as that described by Reichenow in chimpanzees and gorillas and stated by him to be the human parasite.

Failure to transmit the disease experimentally from the case above mentioned to two human subjects led the writers to doubt the correctness of Reichenow's conclusions.

THE ANTIDIURETIC EFFECT OF PITUITARY EXTRACT APPLIED INTRANASALLY IN A CASE OF DIABETES INSIPIDUS.

BLUMGART, H. L. (*Arch. of Int. Med.*, vol. xxix, No. 4, April 15, 1922), reports in detail a case of diabetes insipidus in which pituitary extract was administered subcutaneously, intranasally, by rectum, and by mouth. The comparative efficacy of these measures is charted. In this case and in three others treated later, extract of the posterior lobe applied intranasally checked both polyuria and polydipsia as effectively as hypodermic injection. The extract can be administered either by spraying the nose or introducing pledgets of cotton saturated in pituitrin. Administration by mouth and by rectum had no effect. This marks a distinct advance in the treatment of diabetes insipidus, in which repeated hypodermic injections become exceedingly trying for the patient.

[C. H. L.]

THE VALUE OF QUINIDINE IN CASES OF ATRIAL FIBRILLATION AND METHODS OF STUDYING THE CLINICAL REACTION.

LEWIS, T. (*Am. Jour. Med. Sci.*, June, 1922, vol. cxliii, No. 6), after giving the methods by which the action of quinidine is studied, speaks of the limitations to, and cautions to be observed, in its use. He says that in some cases a single dose of 0.6 gm. may be sufficient, in others repeated doses up to a total of 10 or 15 gm. may be necessary. The precise limits beyond which it is unwise or unprofitable to proceed are still largely unknown. Contrary to some observers, Lewis finds that the effect of quinidine is practically as great when given with or after full doses of digitalis as when given alone. The simultaneous administration of digitalis has the great advantage of keeping the ventricular rate at a comparatively low level throughout the quinidine course.

tion and the eliminating or controlling tachycardia. The ventricular rate often rises after quinidine to from 120 to 160 per minute. This may disturb the patient, and if the auricular rate falls too far a serious accident may occur. Therefore, in cases with high ventricular rates, a combination of quinidine and digitalis is preferable to quinidine alone.

The following contraindications are enumerated:

1. Serious intolerance to quinidine causing sudden loss of consciousness with respiratory standstill. The cause of this, the patient should first receive a small first dose to test tolerance.

2. When there is much dilatation of the heart, as shown by congestion of the liver and veins, the use of quinidine is contraindicated.

3. In cases in which there have been signs or symptoms of recent embolism, the use of the drug invites disaster. Auricular fibrillation favors the formation of clots in the auricular appendices, and the reestablishment of normal action favors the detachment of such clots.

The usefulness of quinidine is limited from the clinical standpoint by several facts. First, the high percentage (70) of failures to restore normal rhythm. Second, by its unsuitability when venous stasis exists. Third, and most serious, by its failure to more than temporarily control the fibrillation.

Lewis concludes that so far the value of quinidine has been greater in adding to our knowledge of fibrillation than as a therapeutic agent. "It is a treatment emphatically for the wards rather than for use in an out-patient department."

[C. H. L.]

THE PREVENTION OF SIMPLE GOITRE IN MAN.

KIMBALL, O. P. (*Am. Jour. Med. Sci.*, vol. cxliii, No. 5, May, 1922).—This article from the Cleveland Clinic is based on the author's experience in goitre prevention in the public schools of Akron. Simple goitre only is included in his report. This type of thyroid derangement is endemic in some parts of the United States, as well as in Europe. The author believes that whatever the fundamental cause of the condition may be, it is directly due to lack of iodine in the organism. This belief is based on Marine's work, and upon the results obtained in the school children tested.

Three thousand eight hundred and seventy-two girls in the Akron schools were examined. Forty-three per cent. had normal thyroids. Forty-nine per cent. showed slightly enlarged thyroids, six per cent. had moderately enlarged thyroids, and 0.2 per cent. had markedly enlarged thyroids.

The following summary of pupils taking prophylactic treatment is striking. The treatment consisted of the administration of 0.2 gm. sodium iodide daily for ten days, repeated each spring and fall.

	Taking.		Not taking.
	Totals.	Per cent.	Totals.
Normal:			
Unchanged	906	98.8	910
Increased	2	0.2	347
Slightly enlarged:			
Unchanged	147	41.9	698
Increased	3	0.3	127
Decreased	659	57.8	134
Moderately enlarged:			
Unchanged	29	20.3	57
Increased	21
Decreased	114	79.7	11
	2,190		2,395

From these figures it appears that the administration of iodine has a marked effect in preventing simple goitre. No ill effects were noted beyond 11 cases of iodide rash, only 5 of which were severe enough to cause the treatment to be stopped. The article is an important one.

[C. H. L.]

SOME PROBLEMS IN INTRACRANIAL DIAGNOSIS.

GORDON, A. H. (*Can. Med. Assn. Jour.*, vol. xii, No. 2, Feb., 1922), describes nine cases which he groups under this heading, including one of cerebral hemorrhage thought to be intracerebral and pathological but actually on the surface and traumatic; one of chronic pulmonary abscess with cerebral abscess and meningitis, wrongly diagnosed as tuberculous meningitis; tumor of the brain developing in a so-called neurotic person, etc. He emphasizes the need of sufficient and systematic examination and the use of great care in interpreting the evidence. The article is difficult to review and should be read by those interested.

THE BOSTON Medical and Surgical Journal

Established in 1828

Published by The Massachusetts Medical Society under the jurisdiction of the following-named committee:

For three years WILLIAM H. ROBEY, JR., M.D.,
ROGER I. LEE, M.D.,
ROBERT B. OSGOOD, M.D.,
JAMES S. STONE, M.D.,
For two years HORACE D. ANSOLD, M.D.,
CHANNING FROTHINGHAM, M.D.,
For one year HOMER GAGE, M.D., Chairman,
EDWARD C. STREETER, M.D.,
EDWARD W. TAYLOR, M.D.

EDITORIAL STAFF.

DAVID L. EDSELL, M.D.,
WALTER B. CANNON, M.D.,
REID HUNT, M.D.,
ROBERT W. LOVETT, M.D.,
FRANKS W. PEARSON, M.D.,
JOHN P. SUTHERLAND, M.D.,
S. BERT WOLBACH, M.D.,
GEORGE R. MINOT, M.D.

WALTER P. BOWERS, M.D., Managing Editor.
GEORGE C. SMITH, M.D., Assistant Editor.

SUBSCRIPTION TERMS: \$6.00 per year in advance, postage paid for the United States, \$7.50 per year for all foreign countries belonging to the Postal Union.

Material for early publication should be received not later than noon on Saturday. Orders for reprints must be sent to the printer with galley proof of paper. Upon written request, authors will be furnished free one hundred eight-page reprints, without covers, or the equivalent in pages in articles of greater length.

The Journal does not hold itself responsible for statements made by any contributor.

Communications should be addressed to The Boston Medical and Surgical Journal, 126 Massachusetts Ave., Boston, Mass.

THE EFFECT ON HEALTH OF ILLUMINATING OR FUEL GAS.

It was formerly contended that the burning of illuminating or fuel gas in living rooms caused an appreciable contamination of the air. This impression persists with some persons at the present time, for the products of combustion are supposed to be poisonous to some extent.

In order to explain the facts relating to the dangers of illuminating gas, Dr. Joseph A. Shears, the sanitary expert of the Department of Health of New York City, has rendered a report which has been published in the *Bulletin* of the department under date of June 24, 1922. This study was inspired by advertisements of a gas company recommending that gas water heaters should be connected to a flue. So far as the toxicity of unburned gas is concerned there is agreement, and the danger of the escape of such gas is quite generally understood, so that all measures which may be employed to prevent such escape or ways for its exit without vitiating the atmosphere are important. So far as the other phase, that of suspected deleterious contaminations of the air, is concerned, it may be surprising to some to learn that carefully conducted experiments tend to show that no damage results from burning gas in apartments occupied by human beings, but on the contrary the quality of the air is improved.

Dr. Shears states that "the combustion of illuminating gas produces, from a chemical standpoint, four different effects on the air taken from a room, mixed with the gas in the burner and discharged back into the room.

"First: The amount of carbon dioxide is increased.

"Second: The amount of oxygen is reduced.
"Third: A very small amount of sulphur dioxide is added.

"Fourth: Dust and bacteria are removed by incineration."

In addition to the chemical action resulting from the union of oxygen with the gas elements, the circulation of air is accelerated and ventilation increased, because the movement of the heated air produces an unbalanced pressure from outside which tends to draw fresh air in through crevices, joints and other openings in addition, to some extent, to that passing through the walls. The heated air in the upper portions of the room escapes in the same ways.

The unhealthful contamination of air in living rooms is usually made up of the excretions from the lungs and skin of the occupants and only to a minor degree by the products of combustion. Excretions are laden with bacteria and decomposing organic matter. It is claimed that exhalations from the lungs account to a large degree for the discomfort felt by occupants of poorly ventilated rooms. The stuffiness is usually attributed to carbonic acid gas, but this gas is found in the purest air, amounting to about four parts in 10,000, and the amount must be increased up to more than 225 parts per 10,000 before the ill effects are produced. Not more than 20 parts in 10,000 are found in interiors usually. For experimental purposes 50 parts in 10,000 have been employed in studying the effect of this contamination, but this was accomplished only with difficulty, for the gas is diffusible. It is therefore contended that the presence of carbonic acid gas is important only so far as it may be an index of other contaminations, for 15 parts in an atmosphere vitiated by human respiration indicates definite pollutions by organic matter. The experiment of Dr. Angus Smith, who shut himself in an air-tight chamber with a lighted candle, and even after the candle failed to burn and 229 parts of CO_2 per 10,000 was developed, felt no ill effect, is quoted, and of Pettenkofer, who found that 100 parts of carbon monoxide in 10,000 parts of air was not injurious to human beings, while one-tenth of this amount of carbon dioxide derived from lungs and exhalations made the air thus contaminated unfit for human use, both conclusions tending to show that the combustion of gas as ordinarily employed has no bad effect on occupants of rooms.

In comparing gas with electric illumination, Dr. Rideal's tests are quoted, which purport to show that under the influence of equal candle power lamps, electricity causes much more eye strain than gas illumination by mantle fixtures.

The thesis is well presented and puts in plain language facts which should be known by the laity. Apparently electricity has no advantage over gas except that unburned gas is poisonous, so that all those forms of gas burners which may, either through carelessness or other reasons, send unburned gas into a room should be connected with a flue, for pilot lights may go out or a draught may extinguish the flame, or the fixture may be defective.

The question of flue connecting is the subject of an investigation by the American Gas Association and its findings will be of great interest. The Department of Health has postponed action, until this report is available, any further than offering the recommendations that no hot water heaters be permitted in bath or other confined rooms unless the same are flue connected and all automatic hot water heaters be flue connected.

ARE THE MEDICAL JOURNALS OF THIS COUNTRY DOMINATED BY THE AMERICAN MEDICAL ASSOCIATION?

In the June issue of the *Illinois Medical Journal* an article credited to *American Medicine* is published, in which it is alleged that a power designated as a star chamber organization is dominating the medical press of the country.

The statement follows that "The fact remains that the medical press of this country is impersonal and timid."

Although the American Medical Association is not named, the description of the dominating organization clearly shows that the A. M. A. is meant.

It is often profitable to see ourselves as others see us and some editors would like to know how our brothers classify us.

Will the *Illinois Journal* and *American Medicine* come more into the open and give the rest of us our rating?

BULLETIN OF THE AYER CLINICAL LABORATORY OF THE PENNSYLVANIA HOSPITAL.

This publication has been suspended for eleven years. It is expected that the series now under way will be permanent.

The first article is contributed by Allen G. Ellis, M.S., M.D., under the title, "Amebiasis." This disease is endemic as far north as Baltimore and Washington and occasionally cases are found in the northern tier of states. The contention is made that all cases of dysentery should call for examination of the patient's stools. House epidemics are not uncommon and are due to contact, flies being the important agent.

Specimens from 8,922 persons in twenty-two states and the District of Columbia showed in

fection by *Entamoeba histolytica* in three hundred and thirty-three persons representing all parts of the country.

Dobell's conclusions that there are six species of amebae living in man but only one, *E. histolytica*, is pathogenic is referred to, and also his statement that evidence of *E. gingivalis* as a cause of pyorrhea alveolaris is not conclusive. The technical details for the laboratory investigation are given.

Emetin seems to be generally employed in the treatment of the disease and in advanced severe cases the drug has been given intravenously one-half to one grain in 5 c.c. normal salt solution. Children under eight years of age bear one-sixth of a grain. It may be necessary to give twelve injections daily. This drug may be used in combination with bismuth iodid by mouth for twelve days. Others use a large dose of bismuth subnitrate by mouth in addition to the intravenous use of emetin.

Several other articles are of interest especially to pathologists. It is hoped that this publication will be continued.

REPORTING DISEASES TO THE HEALTH DEPARTMENT.

The New York City Health Department publishes the report of the conviction of a physician in the Borough of Richmond for failure to report a case of pneumonia. This physician was obliged to pay a fine in addition to the loss of time incident to attendance at court. It would be interesting to know all the circumstances surrounding this court proceeding. If the physician was a defiant offender, sentiment would be in favor of the action taken by the prosecuting officer, but the failure to report a given case may not always mean intentional disregard of the sanitary code. There are times when the strain of work, fatigue and anxiety lead one to forget the commonly accepted responsibility of coöperating with health officials. The report of a prosecution may have a very useful effect in impressing upon physicians the necessity of compliance with health regulations.

In Massachusetts matters of this sort are usually dealt with diplomatically and extreme measures have not often been employed unless the attitude of the offender seemed to indicate a belligerent spirit, for the coöperation of physicians is sought because one may be of great assistance in the maintenance of barriers against the extension of disease. Physicians as a class are not inclined to live according to the letter of the law. They cheerfully render every possible aid, when appealed to, but if a zealous official should try to find occasion for a suit, it is probable that intentional violations of health regulations are sometimes committed by well intentioned doctors.

Practically every operator of a motor vehicle could be convicted in court sooner or later if the letter of the law should be invoked, but police departments are growing more and more discriminating. The same charity should be exercised by officers having charge of the enforcement of regulations which apply to health.

OPINIONS EXPRESSED IN THE INDIANA JOURNAL.

THE *Journal of the Indiana State Medical Association*, June issue, criticises the University of Cincinnati for allowing the surgeons on the staff of the hospital to charge fees for treating private patients in a special ward. The contention is made that a hospital in connection with a university should be used solely for teaching purposes, and that since there may be a sufficient supply of indigent patients for teaching purposes, the use of this hospital for the treatment of paying patients is not fair to the profession at large.

In the same journal it is stated that chiropractors have spent several thousand dollars per year for some time in legislative and propaganda work in Indiana, but the State Society has spent less than one hundred dollars per year through its committee on legislation. The conditions are referred to as "deplorable," and the inference is plain that the editor believes that the expenditure of money has secured favorable returns for the chiropractors.

POLLUTED DRINKING WATER.

Now that the vacation period is on, the usual warning about the danger of polluted drinking water is in order. Although the knowledge that typhoid fever is more often the disease of districts without sewers, visitors to country places occasionally return to urban homes with typhoid fever. Many persons traveling in foreign countries arrange to have antityphoid treatment before leaving home, but visitors to remote localities in our own country are less apt to secure immunity. It happens only rarely that antityphoid treatment fails to protect, but a comparatively few cases of typhoid have been reported even after treatment. Travellers by motor can never be sure that the water supply of a wayside inn, tearoom or inviting spring is wholesome, and milk may have been infected by a carrier. Patients should be warned about water and milk whenever the physician has an opportunity to give advice. If doubtful water is treated with freshly prepared calcium chloride there is practically no danger of contracting typhoid.

The Chicago Department of Health furnishes tablets containing 20 to 30 milligrams of chloride to those who apply for them. One of these

tablets is to be dissolved in a quart of water. This solution will retain its potency for about a week. When using, one teaspoonful of the clear solution may be added to a glass of drinking water and allowed to stand for five minutes. If the water is especially doubtful, two teaspoonfuls may be used. The taste is not objectionable, but taste and the slight trouble is of very little consequence as compared with the suffering, expense and danger incident to typhoid fever, or even an acute gastro-intestinal disturbance.

Dr. Hermann M. Biggs, in a five minutes' health talk sent out by radio, advises that campers boil the day's supply of water and keep it in bottles. Calcium chloride was used in the treatment of drinking water to some extent in France during the war. One pharmaceutical house is reported as manufacturing calcium chloride tablets.

Milk is a somewhat common culture medium for almost all pathogenic germs, and there may be a few people who for the moment forget that boiling destroys the danger of infection.

MEDICAL WORK OF THE UNITED FRUIT COMPANY.

THE Tenth Annual Report of the Medical Department of the United Fruit Company for the year 1921 furnishes much valuable information about the diseases found in the parts of the West Indies and Central America where this company operates, and in addition the report contains an appendix dealing with maintenance of health for the guidance of employees of the company.

The appendix covers eleven pages, is written in direct, non-technical language, and should be very helpful in obtaining for the medical staff of the company the intelligent co-operation of the other employees, without which the fullest benefits of sanitation could not be obtained.

The advice given is of a very practical character. It deals with most of the important medical aspects of life in the tropics, includes preparation for undertaking employment in the tropics, and suitable location for the dwelling in a tropical environment. It describes the desirable type of building, sanitation of the premises, sewage disposal, the means of obtaining safe drinking water, discusses food, clothing and bathing, and gives information about the means of preventing serious diseases and of escaping exposure to insects which might otherwise cause suffering or introduce disease.

In the Letter of Transmittal from Dr. Deeks, general manager of the medical department, it is pointed out that malaria is the most prominent cause of morbidity, but that great progress is being made year by year in sanitary measures for its prevention. Draining, filling, the use

of larvicides, screening of dwellings and the administration of prophylactic quinine are among the methods used, and it is stated that gratifying results have been obtained in the divisions where quinine prophylaxis has been used systematically.

The use of paris green as a larvicide by the method of Dr. Barber of the U. S. Public Health Service has been instituted and will be reported upon later.

At Puerto Castilla in Honduras, where the buildings of the company stood on swampy ground, pure water has been piped in from the mountains and dredging and filling operations have changed the character of the environment, which was exceedingly bad, so that now this port is said to be as sanitary as any in the tropics. The original condition of the locality and its appearance after completion of the work are shown in photographic reproductions.

Alstrim has been practically eliminated by systematic vaccination. All employees have been examined for hookworm and those infected have been treated until cured. Substantial progress has been made in combating venereal diseases as well.

The wise practice of making a thorough physical examination of all prospective employees and of all officers and members of the crews of steamships operated by the company, at the commencement of each voyage, has been continued. At Preston and Limon, where hospital accommodation was insufficient, new hospitals of excellent construction have been built and put into operation within the year.

The medical department consists of port medical officers in New York, New Orleans, Boston and Cristobal, and of hospital and dispensary personnel in the seven operating divisions of the company and those attached to two railroad companies as well.

Some idea of the magnitude of the work can be gained from the figures which follow. The company has under cultivation 395,000 acres of land and undertakes itself to care for the people living in these cultivated areas. It treats not only its employees and their families, but also a considerable number of other individuals living in the same localities who are in no way connected with the company but who would be unable otherwise to obtain either medical advice or hospital treatment.

A comprehensive series of tables gives statistical information about the medical work done in each of the divisions, on the passenger steamers and in the ports. These tables are well worthy of careful study. They show that more than 208,000 cases were treated by the nine medical districts in the tropics with 1050 deaths, a mortality of about five per 1000, or 0.5 per cent. When figured on the basis of the number of persons dependent on the company, the aver-

age rate is 7.44 per 1000, but it varies from 2.75 to 12.62 in different divisions. The average rate compares very favorably with that of the Canal Zone, which, during the ten-year period from 1911 to 1920 inclusive has been 12.49 per 1000 population,* and with rates for large cities in the United States; for example, the average for the ten-year period from 1911 to 1920 inclusive in Boston has been 16.97 per 1000 population.†

The causes of the great differences in the rates for the various medical districts of the company have doubtless been the subject of special study by Dr. Deeks. It seems probable that the rates have been influenced by factors which do not appear in the report. Similarly, the tables show other prominent figures which raise questions of interest.

The table of deaths by disease shows in a striking manner that persons in the tropics are by no means free from diseases prevalent in the temperate zone. For example, the maladies of the respiratory tract taken together, but excluding tuberculosis and cancer, caused 254 deaths, as compared with 167 for all types of malaria. In the former group 157 deaths are attributed to lobar pneumonia, a figure not far below that for malaria. The varieties of tuberculosis account for 91 deaths and acute and chronic nephritis for 86 more.

The relatively small proportion of deaths from infectious intestinal disease, *i.e.*, 24 for typhoid and 33 for all kinds of dysentery, points to good sanitary arrangements. On the other hand, the morbidity from malaria is still high and it is to be expected that subsequent years will show a marked reduction resulting from the campaign being waged against this disease.

The United Fruit Company is to be congratulated upon the showing of its medical department and upon its enlightened policy of working for the prevention of disease among its employees. The company has set a standard which less prosperous business organizations may find it difficult to attain, but health is a fundamental requirement for the worker and failure to appreciate this fact and to guard against illness has, doubtless, ruined many an enterprise in the tropics.

INFANT MORTALITY.

THE American Child Hygiene Association has published its statistical report of infant mortality in cities of over 10,000 population in continental United States. Its first report for 1919 covered 269 cities, in the second report for 1920 519 cities in the death registration were covered, and this last report covers 573 cities with a population of 40,131,121.

*Canal Zone Department of Health Annual Report, 1920.

†Annual Reports of the Health Department of the City of Boston.

There are 664 cities of 10,000 or over in the death registration area, so that the report of 1921 covers 89 percent. of the cities and 94.4 percent. of the population of the death registration area. Cambridge and Lawrence of this state do not appear in the returns.

The figures of the Massachusetts cities from which the statistics are available are as follows:

City.	Population.	General Death Rate All Ages for 1921.	Infant Mortality Rate, 1920.	1921.
Beverly	22,591	10.4	54	39
Brookline	37,748	10.2	63	41
Winchester*	10,485	12.1	61	41
Melrose	18,204	11.1	56	45
Greenfield	15,402	11.1	87	51
Newton	46,054	9.9	61	51
Winthrop	15,455	8.9	40	52
Southbridge	14,245	12.1	58	53
Chelsea	43,184	12.7	63	54
Leicester	19,744	11.8	69	54
Watertown	21,457	7.8	73	55
Attleborough	19,731	13.7	67	59
Northampton (2)	21,351	18.7	86	60
Webster	13,258	11.9	56	61
Newburyport	15,018	14.4	85	62
Arlington	18,665	12.9	67	63
Woburn	16,574	10.7	78	63
Brookton	66,254	10.1	71	64
Braintree*	10,589	15.2	81	66
Northbridge*	10,174	10.2	99	68
Pittsfield	41,763	12.9	65	68
Marlborough	15,028	12.3	69	69
Springfield	129,614	11.3	87	69
North Adams	22,282	12.1	79	72
Lynn	99,148	11.1	82	73
Salem	42,529	13.9	85	74
Haverhill	53,884	12.0	92	75
Worcester (2)	179,754	12.9	85	76
Boston	748,090	13.5	101	77
Somerville	93,091	10.2	80	77
Danvers* (2)	11,108	25.9	65	79
Gardner	16,971	13.4	102	86
Saugus*	10,874	13.4	83	92
Holyoke (3)	60,203	12.3	117	92
Clinton	12,979	13.3	116	95
Lowell	112,759	12.9	135	95
New Bedford	121,217	11.0	122	96
Eastampton*	11,261	12.9	91	101
Plymouth	13,045	17.1	117	101
Fall River	120,485	14.2	129	113

The death rate in those places where there are institutions, which add materially to the figures, should be considered in any interpretation; for, taking Danvers, for example, with the large insane hospital and the comparatively small population, the figures which give the highest death rate for all ages should be construed accordingly. Holyoke is reported to have an institution which adds to the infant mortality. All co-ordinate influences should be studied in any analysis made. It would be interesting to have the Fall River authorities explain the reasons for the unusually high infant mortality rate.

*Place listed as open town, registration in 1920 Census. Early statistics often unreliable.

(2) Important State institutions, for example, affecting crude death rate.

(3) Large institution, for instance, affecting all parts of State, rate higher, and materially affecting rate of mortality rate.

Plymouth, too, has had an abnormally high rate for several years.

Although those in the group included in the low rates may feel complacent there may be reasons for this fortunate state of affairs and these cities may be under obligation to show the others how the results are obtained.

The impressive showing presented by these figures is that there has been a marked average improvement all over the state and Public Health officials should feel encouraged. In all probability the great factor in promoting better conditions lies in the general dissemination of information relating to the causes of infant mortality, and if this is true, there is reason to believe that the people are absorbing the advice on health matters which officials have been sending broadcast during recent years. It is reasonable to believe that still better conditions are to be realized in the future through the application of practices advised by our leaders in health matters.

NEWS ITEMS.

DR. LELAND FRENCH has been appointed District Health Officer in the Berkshire District.

THE REGULAR BI-MONTHLY MEETING OF THE FRANKLIN DISTRICT MEDICAL SOCIETY was held at the Weldon, Greenfield, Tuesday, July 11, 1922, at 11 A. M. Programme: "What the American Medical Society Is and What It Stands For," Dr. H. G. Stetson, Greenfield; "Recent Observations while with the Mayo Brothers," Dr. C. L. Upton, Shelburne Falls.

DR. HAVEN EMERSON has been appointed professor of public health and administration in the College of Physicians and Surgeons, Columbia University, and given the task of working out a plan for the organization of the Institute of Public Health established by the bequest of the late Joseph A. DeLamar.—*Science*, June 30, 1922.

DR. REID HUNT of the Harvard Medical School has been elected on the editorial board for *Physiological Reviews* for 1922.—*Science*, June 30, 1922.

DR. WILLIAM D. WHEELER of Revere, Mass., is leaving for New York to take up an intensive course of training in dermatology and syphilology at the Skin and Cancer Hospital. Dr. Wheeler is junior assistant on the staff of the skin department of the Boston Dispensary.

DR. JOHN LORENZO HELLFON resigned as dean of the Syracuse University School of Medicine on June 15. This resignation terminates the connection which Dr. Hellfon has held with the

teaching staff of the medical school for forty years, during fifteen of which he has served as dean. Dr. Heffron was made dean emeritus.—*Science*.

At the time of the celebration of the centennial of Pasteur's birth, in Strasbough, a congress of hygiene and bacteriology will be held for discussion of questions relating to disease. In order to show the sympathy of Great Britain with the projects of the French committee, a British committee composed of the following members has been formed: Sir Charles Sherrington, chairman; A. Chaston, H. E. Field, Professor Percy R. Frankland, Sir John McFadyen, Professor C. J. Martin, Sir W. J. Pope, Sir James Walker and Sir Ahmoth Wright.—*Science*.

On June 4, at the special invitation of the governors and the medical school, Professor Harvey Cushing took over the directorship of the surgical unit of St. Bartholomew's Hospital and replaced the director, Mr. Gask, for ten days. The compliment was, as it were, a return for a like compliment paid to Mr. Gask last year, when he acted as temporary chief of the Peter Bent Brigham Hospital, Boston, to which Dr. Harvey Cushing, as professor of surgery at Harvard, is surgeon.—*Science*.

During June a nutrition institute was held at Lincoln, Nebraska, and courses on the work of the nutrition class were given at the Summer School of Education conducted by the Cleveland Public Schools. At the latter session there were about forty workers in training preparing for extensions in this work in the Cleveland schools. The Lincoln Institute was the first called by the Department of Medical Inspection in a city. Dr. Katherine Wolff has organized this department effectively and is planning an attack upon malnutrition in the schools. About one hundred were in attendance, including a number of physicians. One of these, Dr. Margaret W. Koenig, has just become a member of the staff of the Children's Bureau at Washington and will begin her government service in the state of Tennessee. A school nurse from South Dakota was present who is doing remarkable work in her district. She is now planning for a traveling clinic which will take care of adenoid and tonsil operations. The work in this institute was recognized by the University of Nebraska and full credit is given for courses taken in it. Dr. William R. P. Emerson gave addresses before the Rotary and Pathfinders' Clubs of Lincoln and a large public meeting as well as dinners and conferences of representatives of the leading child-helping organizations, including the Associated Charities and the Juvenile Court, the educational executives of the university and the public schools, members of the medical and dental associations. In September an institute will be

given in Hartford, under the direction of Nutrition Clinics for Delicate Children, followed by others in Poughkeepsie, Battle Creek, Denver and Honolulu.

OPENINGS FOR JUNIOR MEDICAL OFFICERS IN GOVERNMENT SERVICE.—The United States Civil Service Commission states that there is urgent need for eligibles to fill positions of junior medical officer in the Indian Service and the Coast and Geodetic Survey and that the Commission will receive and rate applications until further notice. Competitors will not be required to report at any place for a written examination, but will be rated upon the subjects of education, training and experience as shown by their applications and corroborative evidence. Full information concerning salaries, etc., and application blanks may be secured from the United States Civil Service Commission, Washington, D. C., or the board of civil service examiners at the postoffice or customhouse in any city.

DEATH RATE IN BOSTON.—During the week ending July 1, 1922, the number of deaths reported was 178, against 150 last year, with a rate of 12.11. There were 15 deaths under one year of age, against 16 last year. The number of cases of principal reportable diseases were: Diphtheria 54, scarlet-fever 21, measles 144, whooping-cough 10, typhoid fever 1, tuberculosis 18. Included in the above were the following cases of non-residents: Diphtheria 7, scarlet-fever 2, measles 1, tuberculosis 1. Total deaths from these diseases were: Diphtheria 4, scarlet-fever 1, measles 1, tuberculosis 16. Included in the above was the following case of a non-resident: Diphtheria 1.

DEATH RATE IN BOSTON.—During the week ending July 8, 1922, the number of deaths reported was 180, against 149 last year, with a rate of 12.29. There were 25 deaths under one year of age, against 25 last year. The number of cases of principal reportable diseases were: Diphtheria, 44; whooping cough, 21; scarlet fever, 21; typhoid fever, 1; measles, 98; tuberculosis, 40. Included in the above were the following cases of non-residents: Scarlet fever, 4; tuberculosis, 2. Total deaths from these diseases were: Diphtheria, 3; tuberculosis, 21. Included in the above was the following case of a non-resident: Tuberculosis, 1.

DR. ROBERT RICE, a fellow of the Massachusetts Medical Society since 1920, died at the Hale Hospital, Haverhill, July 9, 1922, at the age of fifty-two.

He was born in Scotland, coming to this country twenty-five years ago. He graduated from the Hahnemann Medical College and Hospital of Philadelphia in 1908 and settled in Haverhill, where he did a general practice and served on the staff of the hospital in which he died.

He is survived by his widow.

THE VALUE OF BASAL METABOLISM DETERMINATIONS IN THE DIAGNOSIS AND TREATMENT OF HYPERTHYROIDISM.*

BY HENRY F. STOLL, M.D., HARTFORD, CONN.

Assistant Visiting Physician and Syphilologist to the Hartford Hospital; Visiting Physician to the Municipal Hospital.

At a time when so many voices are heard decrying the prominence given today to laboratory diagnoses and the seeming decadence of careful clinical observation, one must examine with great care each newly advocated diagnostic method. One may postulate three requisites that should be fulfilled before a new procedure is accepted: (1) Is there need of such a test? (2) Is the proposed test trustworthy? (3) Is it sufficiently simple of performance to make it generally available? Applying these criteria to the subject under discussion, is a test for the detection of thyroid dysfunction needed? For years physicians the world over have recognized hyperthyroidism by its clinical manifestations alone, and a fourth-year medical school student can make a diagnosis of thyrotoxicosis in the patient with protruding

eyes, tremor, rapid pulse and struma. Why employ a test requiring considerable time and a very careful technique? This question is very pertinent when a man of Crile's standing and large experience with hyperthyroid cases finds his clinical judgment the best guide.¹ But do most physicians possess such diagnostic acumen? Plummer² says: "The phenomena of mild exophthalmic goitre are so much like the psychoneurotic manifestations due to lack of assurance, that the thyroid is frequently resected for the latter condition." A well-known internist, after studying a group of so-called "neuro-circulatory asthenia" patients in the army, was convinced that the condition was due to over-functioning of the thyroid gland. The basal metabolism in a similar group, however, was subsequently found to be normal, thus excluding hyperthyroidism.

It is the border-line case, not the classical picture that puzzles us. Particularly difficult is it to decide whether the symptoms in a patient with slight enlargement of the thyroid are due to "nerves" or to increased secretion of the thyroid. Such a case was Mrs. S., aged 39, who was referred to me in June, 1921, to determine whether she had hyperthyroidism. Nine months previously she first noticed that the thyroid was slightly enlarged. One or two friends also commented on this and she immediately began to worry. Her sister noticed a variation in size at different times. Mrs. S. had always been of a nervous temperament and perspired rather easily. There had been no loss of weight re-

*Read before the One Hundred Thirtieth Annual Meeting of the Hartford County Medical Society.

cently; in fact, she had gained slightly. Of late there had been slight insomnia because she feared she was developing a goitre. The patient was a large, well-nourished woman, with moderate flushing of the skin and slight general enlargement of the thyroid. Pulse 108, no tremor, exophthalmos, thrill or bruit. I felt that the nervousness was due more to worry over the thyroid enlargement than to the over-functioning of the gland. I saw her occasionally through the summer and fall; the nervousness slightly increased, she began to tire easily and her appetite was not as good. Her pulse was about 90 most of the time. Early in October the basal metabolism was plus 26 per cent. (Chart 1.) Radium was not applied by Dr. Heublein until nearly two months later. A slight systemic reaction followed and some increased swelling of the gland. Three weeks later she was no better and the basal metabolism at this time gave practically the same result, plus 25 per cent. One month later, at which time there was some clinical improvement manifest, it had fallen to plus 20 per cent. and six weeks later, at which time the patient was better "in all ways," it was plus 16 per cent. Though the size of the gland had not materially changed, she was much stronger, breathed more easily, slept better, was much less nervous and perspired less easily.

It is often difficult in the presence of an adenoma that has persisted for years, to determine whether it plays any part in the symptoms. At the Mayo Clinic it was found that the adenomatous goitre did not cause toxic symptoms till the latter half of the third decade and on an average seventeen and one-half years after the appearance of the goitre.

Mrs. C., a woman of 54, was first seen Nov. 3rd, 1921. She had had a large adenoma of the thyroid for a number of years. Several months previously she was examined by an internist of ability, who did not believe there was any relationship between her nervousness and weakness and the thyroid. Very soon thereafter she was seen by a surgeon who has had considerable experience with hyperthyroid cases. He not only thought she was suffering from a toxic adenoma, but he considered her too toxic even for ligation, and advised radium. This was applied in August, and again in October, 1921, with some clinical improvement, but no basal metabolism estimation was made until November 3rd. At this time, notwithstanding two radium treatments, the basal metabolism was plus 35 per cent. Following the radium she improved considerably, but she still suffered from palpitation, nervousness, weakness and a rapid pulse, and was much below her normal weight. Six weeks later (Dec. 21st), there was little change, either in her general condition or her metabolic rate, which was plus 22

per cent. This case illustrates that a perfectly well behaved adenoma may, without apparent provocation, suddenly begin to flood the system with an excess of thyroxin. If at the inception of symptoms the basal metabolism be ascertained, treatment can be instituted before the irreparable damage present in the case just recounted takes place. Like tuberculosis, little can be accomplished when the diagnosis can be made by the man on the street.

Mrs. W., a widow, aged 54, complained of dyspnoea and palpitation. She was referred to me because her physician thought that possibly she might have hyperthyroidism as she had a moderate enlargement of the thyroid and a slightly elevated blood pressure. Her basal metabolism, however, was normal, suggesting that possibly digitalis rather than radiation of her thyroid was indicated. Even if the basal metabolism had been moderately increased in this case it would have been impossible on this evidence to incriminate the thyroid, as cardio-renal patients with dyspnoea often show an increased rate.

From the cases already cited it is apparent that the estimation of the activity of the thyroid by clinical means alone is frequently erroneous. Even when the clinical diagnosis is unquestioned, the problem is but half solved. How toxic is the patient? Shall lobectomy be performed or would a preliminary ligation or, perhaps, x-ray or radium be safer? These questions the surgeon familiar with such cases can usually answer. All appreciate that rapid loss of weight, a rapid fibrillating heart and diarrhoea indicate a severe toxæmia; but there are border-line cases where even the man of large experience is sometimes sorely puzzled. If the degree of toxæmia is underestimated, a fatality may ensue. As an aid in estimating the degree of toxicity basal metabolism determinations have proven of a great deal of help. Pemberton³ states that "the degree of loss of strength and weight, and the height of the basal metabolic rate, taken separately, are only relative criteria of the operability of patients with exophthalmic goitre; but taken together, and in relation to the phase of the disease, they become the basis on which an opinion is formed." Leahy⁴ believes that "basal metabolism as a diagnostic measure, although subject to error in estimation and interpretation, is probably more constantly reliable than many of our other laboratory measures." The clinical picture should always be studied in conjunction with the basal metabolic rate as there may be certain symptoms that stamp the case as a poor risk, though the metabolic rate may suggest only a mild toxæmia. In such a case, to disregard the symptoms and do a lobectomy because the metabolic rate was below a certain figure would be to

court disaster. The basal metabolic rate alone, therefore, will not guarantee the safety of any surgical procedure. Leahy feels, however, that when there is no clinical evidence of severe toxicity, and no complication (heart and kidney), partial lobectomy, unprecedented by ligation, may be undertaken when the basal metabolism is not over plus 35 per cent. Metabolic rates between plus 35 per cent. and plus 50 per cent. require judgment, based upon a large experience, to decide between ligation and partial lobectomy.

With rates above 50 per cent. Leahy considers primary ligation safest. When the B. M. is over plus 75, extreme caution in any surgical procedure is demanded. A progressively increasing B. M. rate is indicative of a so-called crisis and is a contraindication to operation. In deciding as to the operability of toxic goiters, at the Mayo Clinic, the greatest weight is attached to three things, viz., the loss of strength, loss of weight, and the metabolic rate. The average increase in the metabolic rate in cases suitable for a primary lobectomy was plus 36; of the groups requiring a primary ligation the average rate was plus 51 per cent. Those patients who, for some reason or other, were deemed not suited for immediate operation, and in whom two ligations and a rest period preceded lobectomy, had an average B. M. of plus 63 per cent. In estimating the degree of loss of strength, the use of the coefficients, 1, 2, 3, and 4, has been suggested. For reasons hereinafter explained, I would suggest 10, 20, 30, and 40 be used to indicate the loss of strength. In expressing loss of strength numerically, it is impossible to eliminate the element of personal equation, yet this can be minimized to a large degree if it be assumed that loss of strength 40 signifies confinement to bed; loss of strength 30, ability to be up though not able to work, and with great loss of strength in the quadriceps muscles manifest especially in stair-climbing; loss of strength 20, the ability to work, but with great exhaustion; loss of strength 10, slight but definite increase in fatigability. In the majority of cases the degree of the loss of strength, loss of weight, and the increase in metabolic rate roughly agree. When this is not the case the deviating factor is often offset by one or both of the others. For example, patients are occasionally seen who seem more toxic than the B. M. would indicate. In such instances the loss of strength and loss of weight are usually extreme.

If in some way it were possible to obtain a numerical expression of the combined loss of weight, loss of strength, and the increased metabolic rate, the result might be more accurate than the B. M. rate alone. This might be referred to as the total toxicity. Applying this to Pemberton's averages (Chart 2), and mov-

ing his decimal point one place to the right, under loss of strength, to comply with the plan suggested above, we then add the loss of strength, loss of weight, and increased metabolic rates together. It is then apparent that primary resection was done when the total toxicity averaged 64; that ligation was the operation of choice when the total toxicity rose to 80, but that when it exceeded 100 two ligations and a rest period preceded removal of the gland. Theoretically, such a formula might be of value unless the numerical expression of loss of weight would prove too variable. It at least would tend to focus more attention on the importance of loss of weight and strength in determining operability.

Two cases, seen recently, demonstrate that the metabolic rate may give a truer idea of the gravity of the case than the clinical picture. Mrs. G., aged 39, first noticed enlargement of the thyroid 14 years ago, during her first pregnancy at about the sixth month. The swelling subsided after confinement to a considerable degree. This was repeated with each of the three succeeding pregnancies. Since the last there has been a well-marked adenoma, and she had never been quite as well, though toxic symptoms had been present only six months. During the nine days patient was awaiting operation, the pulse was rarely over 90 and usually between 80 and 85. The B. M. was plus 64 per cent.; as this was higher than her general picture suggested, and as the results of ligation in toxic adenoma are disappointing, lobectomy was undertaken, but the patient died before its completion. Had we determined her "total toxicity" (64 plus 20 plus 25), we would have realized that she was in the group in which any operation is extremely hazardous.

Mrs. Z., aged 40, had been in her usual health till 8 weeks before, when vomiting began. For the same period she had suffered from a frontal headache. She had had marked trembling of the whole body for three weeks, especially when nervous. For six years she had had a goitre. The patient was very nervous and excited. There were no eye signs. The face appeared rather puffy and "myxedematous." The right lobe of the thyroid was about the size of "turkey's egg," the isthmus and left lobe were apparently not enlarged. There was marked tremor of the hands. Unlike the preceding case, she was very excitable and ran an erratic pulse. It was not possible to ascertain the loss of weight nor to estimate the loss of strength. The B. M. done by Dr. Whittles and Miss Flynn, October 24, 1921, was plus 57 per cent. Approximately two weeks later it was repeated by Dr. Wentworth and again found plus 57 per cent. Ten days later a rather extensive resection was performed, following which the patient experienced a severe

reaction from which she died the next day.

The claim has been made that the pulse rate gives as accurate a picture of the degree of toxicity as the basal metabolism. The charts of these two cases demonstrate that this is not always true. In fact, these cases were quite different clinically, though in each the basal metabolic rate was considerably higher than that obtained in cases generally considered as suitable for primary lobectomy. (Chart 3.)

The toxic patient, in whom a primary ligation is done, will in all probability need further surgery; but when? Shall we tell him to return "in a couple of months," or take the basal metabolism every two weeks, and advise the next operation when the fall in rate ceases?

Is the test referred to as the "Basal Metabolism test" trustworthy? It is only a short time since we were told that excessive thyroid secretion could be determined by the injection of epinephrin and by study of the blood sugar curve following the ingestion of a certain amount of glucose. These tests have proven disappointing. On what sort of a foundation does the test under discussion today rest?

Many years ago it was established that the end-result of all bodily activities was the production of heat. It was also determined that under identical basal conditions normal individuals of the same age, sex, and body surface area gave off the same amount of heat.

As the actual measurement of the heat produced was exceedingly complicated, requiring the use of a very large and expensive apparatus, calorimeter, it was quite impractical for general use. Inasmuch as the transformation of muscular and glandular activity into heat depends upon oxidation, the determination of the amount of oxygen consumed in a given period enables one to state at what intensity the body metabolism is taking place. For a number of years, in computing the B. M., the oxygen consumed and the carbon dioxide given off were determined by the method of gas analysis. The technical aspects of this method were so great that it was only carried out in a few of the larger clinics. Thanks to Benedict, a relatively simple and portable apparatus was devised, with which one can quickly and accurately determine the oxygen consumption. Tables have been compiled from which one can easily compute the normal metabolic rate when the height, weight, sex and age are known. The trustworthiness of this method has been thoroughly established, if all the details that experience has shown necessary are carefully carried out. Boothby⁵ warns that "if the conditions for determining a true basal metabolic rate are not obtained or the method of determination is not carried out with the care necessary to eliminate even slight errors, one of the most valuable methods of diagnosis and

classification of disease will fall into discredit from the discordant results obtained."

We may now briefly discuss the last of the three points raised at the beginning of the paper. Is the test sufficiently simple of performance as to make it generally available?

There are several small, easily portable apparatuses on the market that accurately measure oxygen consumption. The Handy-Sanborn was used in all of the tests here reported. Because of the ease with which it can be carried about it may be used equally well in hospital, private home, office or dispensary, providing a rest period of at least one-half hour precedes the test. With very toxic patients, however, the test is better made in the home, or after resting quietly in the hospital, as the exertion of going to the office may increase the rate by over 10 per cent. If very toxic cases are tested in the office they should make the trip by automobile, and rest at least one hour before the test is run. In the very nervous it is advisable to make a "dummy test" the day before the real one, and whenever there is any question about the result, it should be repeated the next day. Concerning the interpretation of results, Benedict⁶ says, "The simplification of the technique is dangerous when it makes it possible for the tyro to secure measurements, which frequently neither he nor his associates are in a position to interpret intelligently, and from which it is possible for him to draw deductions that are not only erroneous, but since they not infrequently make for or against operative procedure, may actually be of serious harm." Continuing, he says, "Unfortunately, the intellectual training of the operator has by no means progressed as rapidly as has the simplification of the technique."

In concluding I will review somewhat in detail the case of Mr. D., as it illustrates the value of B. M. in diagnosis, and as a guide to treatment.

Mr. H. D., aged 45, was first seen September 14, 1921, complaining of being shaky; weakness and trembling. His occupation, that of an insurance agent for an industrial company, necessitated walking several miles each day, and going up and down stairs a great many times. About ten weeks previously he began to feel weak. He continued at work through July, during the exceedingly hot weather, and shortly, in addition to his weakness, began to notice trembling in the legs after climbing stairs. His hands also trembled. He perspired freely, especially about the knees, so much so that his trousers would become wet. As has been stated, the weather at this time was exceedingly hot. His appetite failed and for the past two months he hiccoughed a great deal; the attacks never lasting over three minutes. Recently he had slept poorly. It had been noted by his brother that his complexion was be-

coming muddy. He had lost 16 pounds in a year and during the past three weeks, though eating a good deal, had lost four pounds. For several months he had had nocturnal polyuria (two or three times), and sixteen years previously he was ill with "kidney trouble." The patient looked very ill, his color was rather earthy, his breath fetid; he was very weak and there was coarse tremor of the hands. There was a suggestion of prominence to the eyes, and the right lobe of the thyroid was very slightly enlarged. My attention was particularly focused on the tonsils, which were extraordinarily large and very septic. The day urine 945 c.c., night urine 690 c.c., the specific gravity was not fixed; there was no albumin and an occasional cast. Blood uric acid 7, urea nitrogen 24. The whole picture was thought to be dependent upon his very septic tonsils and secondary kidney damage. Prior to his coming under my observation he was seen by another physician, who suspected an early paralysis agitans, because of his marked tremor and rather expressionless face. His pulse was not especially rapid, 90 per minute, and according to his family physician, it was practically always under 90. The blood pressure, Wassermann, hemoglobin and red count were not remarkable. The leucocytes were 12,000 with 46 per cent. lymphocytes. He was referred to Dr. Warfield T. Longcope. The excitement and fatigue, incident to the trip to New York, was sufficient to bring on marked fibrillation, and at Dr. Longcope's examination the pulse varied from 130 to 150; the patient was also perspiring profusely. Dr. Longcope made a diagnosis of hyperthyroidism and because of the evident toxicity and myocardial damage advised x-ray rather than surgery. An electrocardiogram, taken by Dr. Eggleston at this time, showed evidence of myocardial disease and auricular fibrillation. Being interested in collecting medical opinions, Mr. D. consulted another clinician, of his own choice, while in New York, who assured him that the diagnosis of hyperthyroidism was unwarranted

and advised removal of the tonsils. Because of the relatively slight enlargement of the thyroid, and the very obviously diseased tonsils, this latter opinion was concurred in after his return to Hartford by a surgeon who has seen much of hyperthyroid disease. The truth of DuBois' statement, that the basal metabolic rate is more apt to be correct than nine out of ten consultants, was demonstrated by this case, as two basal metabolism determinations, made within three days, gave plus 55 per cent. and 56 per cent., respectively. (Chart 5.) The "total toxicity" was estimated at 96. Radium (200 m.gm., one-half inch, 13 areas, 60 min.) was then applied over the thyroid and tonsils, and six weeks later radium was again applied directly to the tonsils through the mouth, 100 m.gm., 45 min. each tonsil. Three weeks after the first application of radium, the B. M. had fallen from plus 55 per cent. to plus 38 per cent., and there was a slight improvement in the pulse rate. There had been no gain in weight at this time though the patient felt better. Two months after the application of the radium the B. M. was normal and the tonsils were about one-quarter their original size. One month later the B. M. was minus 18 per cent., and at this time thyroid gland in small doses was begun, gr. three-quarters daily; three weeks later it was minus 14 per cent., so the thyroid was increased to gr. one and one-half daily. Three weeks later still the B. M. was still below normal so the thyroid was increased to gr. 4 per day, and in three weeks the B. M. was again normal. Thyroid was then stopped and one month later it had dropped to minus 18 per cent. In this case the pulse follows the B. M. very closely and the weight increases as the metabolic rate falls. As is usual in similar cases, Dr. Henklein thought a second radium treatment would be necessary after an interval of six weeks. At the expiration of this time, although Mr. D. was better, he was far from well, but inasmuch as the B. M. rate was steadily falling it was deemed advisable to postpone the treatment for a time. It is in-

interesting to speculate as to the degree of hypothyroidism he would have developed if the second application of radium had been made, as would have been the case had no B. M. determination been made. At present Mr. D. is in excellent condition, the slight prominence of the eyes has entirely subsided; the thyroid, which was only slightly enlarged, is, possibly, a trifle smaller. The reduction in the size of the tonsils has been as surprising as gratifying. The blood uric acid and urea are normal, and an electrocardiogram taken recently by Dr. Starr is normal in all respects. Mr. D. thinks he feels better the past month without thyroid than he did during the preceding month when he was taking it.

As deviations from the normal in basal metabolic rates are not always dependent upon diseases of the thyroid, a very careful history and painstaking examination should always precede the B. M. determination. This clinical study, if sufficiently thorough, will suffice to make the diagnosis in many cases. There are border-line cases, however, where the metabolic rate will prove very helpful. In conjunction with the usual clinical signs of toxicity the basal metabolic rate assists materially in deciding what form of therapy is most advisable. As changes in the metabolic rate frequently precede changes in the clinical picture, metabolism estimations at stated periods afford a valuable means of checking any therapeutic measure, either medical or surgical.

NOTE ON MOISTURE ABSORBING EFFICIENCY OF CARBON DIOXIDE ABSORBENTS FOR METABOLISM APPARATUS.

By ROBERT E. WILSON, BOSTON.

Director of the Research Laboratory of Applied Chemistry of the Massachusetts Institute of Technology.

ALL those interested in the use of metabolism apparatus of the Benedict type will appreciate greatly the recent articles in this Journal* by Dr. Paul Roth of Battle Creek. There are, however, a few points with regard to the paper on "Moisture Absorbing Efficiency of CO₂ Absorbents" which should be mentioned as supplementary to the interesting data there presented.

It is unquestionably true that Wilson soda lime, designed as it was to have maximum CO₂ efficiency *without caking*, absorbs very little moisture from the air and maintains a relative humidity throughout the apparatus of about 80 per cent. at all times. Dr. Roth's article appears to imply, however, that this failure to absorb moisture as well as CO₂ is a fundamental defect in such an absorbent, which is certainly not the case. It is true, to be sure, as Dr. Roth points out, that the presence of this moisture in the air may cause an error of from 1½ to 3 per cent. (depending on the temperature) in calculating by the customary methods the true volume of oxygen consumed. This error is, however, caused *solely* by the use of correction tables which were calculated on the basis of reducing warm *dry* air to standard conditions of temperature and pressure, whereas correction tables of identical accuracy may be drawn up for any other constant humidity, either absolute or relative.

Fortunately, extensive humidity equilibrium measurements made in this laboratory and elsewhere on Wilson soda lime indicate that material of a given water content maintains substantially constant relative humidity at all ordinary temperatures, and that as marketed (16-18% H₂O) this relative humidity is 80 per cent. It does absorb small amounts of water from the nearly saturated air which reaches it in the metabolism apparatus, but has never been found to give humidities above 90 per cent. in service. The average values reported by Dr. Roth were slightly lower than this, but in the course of correspondence Dr. Roth has attributed this to allowing some of the moisture to escape from the soda lime before use, and he reports recent values on half-used soda lime of 79.1%, 81.8% and 82.8%, which confirms the above conclusion. Similar measurements on caking absorbents which contain larger percentages of caustic soda, indicate humidities varying from 0 to 20 per cent. or higher, the higher quantities being due to the water seal, or to partly used material.

It is therefore apparent that the average error made in correcting the volumes measured with Wilson soda lime by using a correction table calculated for 80 per cent. humidity, is actually *less* than that made by using a caking absorbent and correcting on the customary assumption of 0 per cent. humidity. In both cases, however, the accuracy is well within the limits of error of the measurements.

In order to retain the advantage of non-caking absorbents for CO₂ and yet eliminate the errors due to calculating on the basis of the ordinary tables, the following correction table has been constructed by modifying Clarke's table* to allow for 80 per cent. relative humidity

*Clarke's table given in Dr. Roth's article was originally based on a similar table by Carpenter. Since the writer's table was calculated his attention has been called to a somewhat similar table calculated by McKesson for 67% humidity in a recent booklet describing his Metabolizer. The directions there given for drying the soda lime will, however, lead to erroneous results.

*Pw—pressure of water vapor at the temperature in question.

**Table calculated by Tyler Fuwa on basis of table by E. H. Clarke.

in the warm air as measured. This change decreases Clarke's correction factors by amounts varying from .013 at 15°C. to .030 at 30°C.

While the use of a drying agent such as calcium chloride in conjunction with Wilson soda lime is possible, the two should not be placed close together, because the CaCl_2 simply exhausts itself in absorbing water from the soda lime, which latter needs the high moisture content in order to have its maximum efficiency. It is much better to use all the available space for the CO_2 absorbent only.

In addition to their non-caking qualities, CO_2 absorbents which do not absorb moisture have two other important advantages, in that (a) the heat evolved in the absorbent is *much* less, thus preventing undesirable temperature fluctuations during the test; and (b) there is no need to use a moistener in the mouthpiece, as is otherwise required to make the dry air comfortable for breathing by the patient.

From the foregoing it is obvious that the water content of Wilson soda lime should be kept above 14 per cent., both in order to insure high CO_2 absorbing efficiency and to keep the humidity within the range for which the correction table is calculated.

The accumulated experience of a considerable number of experimenters with metabolism apparatus, confirmed by Dr. Roth, indicates that the use of caking absorbents by themselves is impracticable, if not an unmitigated nuisance. By the use of the foregoing correction table, however, all the advantages of the non-caking, non-heating absorbents can be obtained without any sacrifice whatever in the accuracy of the results.

THE MORTALITY FROM DIABETES.

By FREDERICK L. HOFFMAN, LL.D., NEWARK, N. J.

Consulting Statistician, Prudential Insurance Company of America.

IN a recent discussion of the mortality from biliary and urinary calculi I tentatively presented the subject in its international aspects to draw attention to the apparent geographical distribution of these affections.* The results of a similar inquiry into the local incidence of diabetes seem to be deserving of a brief discussion, primarily for the purpose of suggesting further research into certain etiological aspects of this disease which, as yet, have received exceedingly superficial consideration. It is clearly realized, of course, that the diagnosis in diabetes is much more difficult than in the case of acute infections or readily recognizable chronic diseases. Few diseases have a more technical literature than diabetes, and it is clearly apprehended that serious objections

may be raised against the use of crude statistical methods in determining its probable geographical distribution. But in the absence of a previous extended international comparison of available death rates it is hoped that the following observations will be received, in due appreciation of the intrinsic difficulty of considering the subject statistically from a strictly scientific point of view.

It is to be assumed that in the mortality returns of diabetes, both diabetes insipidus and diabetes mellitus are included, while, of course, it is the latter form of the disease which is the more important. Errors in diagnosis without a chemical examination of the urine are no doubt of fairly common occurrence, but how far this has been determined by autopsy findings is not, apparently, a matter of trustworthy record. The fact, however, that diabetes is, as a rule, a disease of prolonged duration, minimizes the chances of error in terminal diagnosis to a considerable degree.

It may not be out of place in this connection for me to direct attention to an extremely suggestive discussion on "The Causes of Death in Diabetes," by Dr. Elliott P. Joslin, of Boston, delivered before the New York Academy of Medicine, December 21, 1915. Dr. Joslin, in an analysis of the end-results of 945 diabetic cases, ascertained that 921, or 97.5 per cent., had been traced, and 425, or 46.2 per cent. of the traced, had died. The actual causes of death were ascertained in all but five of the 425 cases. There were 147 cases without coma, and 273 cases with coma. Of the former cases, 17 suffered from cancer, 16 from pulmonary tuberculosis, 62 from cardio-renal and vascular diseases, and 36 from infections of various kinds, including 15 cases of pneumonia. Of the deaths, 15 occurred in hospitals, and 258 occurred outside of hospitals. It is suggestive that of the 17 cases of cancer complicated by diabetes six should have been cases of cancer of the liver. It is explained that cancer apparently developed after the diabetes in eight cases, and may have developed before or coincident with the diabetes in seven others. It is such investigations as the one by Dr. Joslin that suggest the most fruitful field for statistical inquiry into the etiology of diabetic affections.

The exceptional frequency of diabetes among Jews is beyond the range of controversy. In a recent investigation by a Dutch authority on the vital statistics of Amsterdam, earlier investigations are sustained by additional evidence derived from a wide range of information. Countries with a large Jewish population are, therefore, likely to have a high rate of incidence, attributable primarily to racial influences. Subject to these very fragmentary observations, attention is directed to the following table, giving diabetes death rates for

*New York Medical Journal.

specified countries, in most cases for the five years ending with 1919:

TABLE 1.

MORTALITY FROM DIABETES IN FOREIGN COUNTRIES.
(Rates per 100,000 population.)

	Rate		Rate
Island of Malta.....	38.4	Spain	5.8
Isle of Man.....	18.1	Ceylon	5.6
Island of Guernsey.....	16.1	Italy	5.1
Bermuda	15.2	Island of Mauritius.....	5.6
New Zealand	14.6	Uruguay	5.0
Holland	12.5	Hawaii	4.6
England and Wales 11.8		Trinidad and Tobago	4.3
Province of Ontario (Canada)	11.5	Newfoundland	3.6
Egypt	11.3	Cuba	3.2
Australia	11.3	Japan	2.8
Nova Scotia	10.5	Straits Settlements.....	2.6
Tasmania	10.1	Chile	2.4
Scotland	9.7	Porto Rico	2.3
Ireland	8.3	British Guiana	1.8
Union of So. Africa	7.7	Grenada	1.6
Province of Alberta, (Canada)	6.7	Province of Tucuman (Argentina Republic)	1.6
Province of Manitoba (Canada)	6.0	Jamaica	1.5
		Bahamas	1.1
		Venezuela	1.0

The range in relative frequency is really extraordinary, reaching a maximum of 38.4 per 100,000 of population in the case of the Island of Malta, 18.1 for the Isle of Man, and 16.1 for the Island of Guernsey; and a minimum of 1.5 for the Island of Jamaica, 1.1 for the Bahamas, and 1.0 for Venezuela. The average diabetes death rate for the United States Registration Area is 16.4 per 100,000 of population, practically the maximum rate attained for the countries or islands which rank highest in the foregoing table. The American death rate is decidedly above the normal average of 11.8 for England and Wales, and while unquestionably somewhat affected by the relatively large Jewish population in our large cities, this factor cannot be considered as primarily responsible for the marked excess. Since diabetes is essentially a disease of adult age, the following table of death rates, at ages 20 and over, is included for a number of important countries.

TABLE 2.

MORTALITY FROM DIABETES, AGES 20 YEARS AND OVER.
(Rates per 100,000 population.)

	Rate
Island of Malta.....	67.8
New Zealand	23.2
Holland	21.0
England and Wales.....	21.3
Australia	17.8
Nova Scotia	15.8
Tasmania	16.1
Scotland	17.0
Ireland	12.7
Union of South Africa.....	13.7
Uruguay	10.3
Province of Alberta, Canada.....	9.5
Province of Manitoba, Canada.....	8.8
Italy	8.6
Province of Tucuman, Argentina.....	3.3

This table does not change materially the previous conclusions as to the relative frequency of local incidence.

To the foregoing I add a few relative rates, according to sex, limiting the comparison to ages 20 and over. For Malta the male diabetic death rate is 62.8 per 100,000 of population; for females, 72.8. For New Zealand the rates are 22.3 and 24.1, respectively; for Holland, 18.7 and 23.1; and for England and Wales, 23.7 and 18.2. For Australia the males have a rate of 15.3, while the females have a rate of 20.4; and in Tasmania the same excess in the female mortality is met with, the rates being 13.4 and 18.8, respectively. For Scotland the male rate is 16.1 and the female rate 17.8; while for Ireland the respective rates are 14.4 and 11.1 per 100,000 of population. In Italy women are distinctly less liable than men, the rate for the former being 6.8, while for the latter the rate is 10.5; but in Uruguay this position is reversed, the male rate being 8.2 and the female rate 12.6 per 100,000 population. In a general way, therefore, this analysis would seem to support the conclusion that women are somewhat more liable to diabetic affections than men.

For more restricted urban areas the rates are probably more trustworthy and significant. The third table will show the diabetic death rate of the principal foreign cities for which the rates or information could be obtained, most of the data being for the five years ending with 1918 or 1919:

TABLE 3.

MORTALITY FROM DIABETES IN FOREIGN CITIES.
(Rates per 100,000 population.)

	Rate
Berlin, Germany	17.9
Copenhagen, Denmark	17.1
Amsterdam, Holland	15.9
Paris, France	15.5
Barcelona, Spain	14.9
Florence, Italy	14.1
St. John, New Brunswick.....	13.4
Christiania, Norway	13.2
San Salvador, Salvador.....	13.0
Colombo, Ceylon	12.5
Victoria City, British Columbia.....	11.5
Basel, Switzerland	11.4
Montreal, Canada	11.2
Toronto, Canada	11.1
Montevideo, Uruguay	10.6
Edinburgh, Scotland	10.4
London, England	10.3
Belfast, Ireland	9.9
Glasgow, Scotland	8.8
Madrid, Spain	8.8
Turin, Italy	7.2
Milan, Italy	6.3
Mexico City, Mexico.....	5.4
Manila, P. I.	4.5
Singapore, Straits Settlements.....	4.3
Tokio, Japan	4.1

To facilitate a convenient comparison it may be stated that the normal diabetic death rate

of New York City for the five years ending with 1919 was 19.8 per 100,000 of population, or higher than the maximum rate, according to the table, reported for the city of Berlin, or 17.9 per 100,000, or for Copenhagen, Denmark, for which the rate is 17.1; but for Amsterdam, Holland, the rate is 15.9. The minimum rates are reported for Tokio, Japan, or 4.1; for Singapore, or 4.3; for Manila, P. I., or 4.5; and for the City of Mexico, or 5.4.

In the case of the cities, as in the case of the countries, the rates do not undergo a material change in their relative positions when reduced to the age period 20 and over. For a few of the cities for which the information is available the following rates, according to sex, at ages 20 and over, are of interest: Berlin, Germany, males 31.4 and females 20.8 per 100,000; Copenhagen, Denmark, males 28.1 and females 20.9; Florence, Italy, males 27.1 and females 14.5; Christiania, Norway, males 24.4 and females 14.5; Victoria, B. C., males 12.0 and females 15.3; Montevideo, Uruguay, males 13.7 and females 25.9; London, England, males 16.8 and females 14.8; and Singapore, Straits Settlement, males 5.5 and females 6.7.

The results of this analysis would seem to contradict the previous conclusion regarding the higher frequency of diabetes in the case of females, but this may possibly be explained by a higher incidence of diabetic affections among women in rural districts, who, of course, make up the larger portion of the population of the countries considered.

It is evident that a much more extended inquiry is necessary to determine the facts with scientific precision. Whether diabetes is on the increase or not is secondary to the question that the disease is widespread among the well-to-do and the prosperous, among whom hypernutrition and excess in weight emphasize abnormalities of metabolism as the result of erroneous dietary or other habits. Diabetes unquestionably is closely correlated to excess in weight, and the prevention of the disease is, therefore, within the range of possibility in a considerable number of cases. The apparent increase in diabetic affections would seem to coincide with the increase in the death rate from cancer. Years ago Manders and others held that diabetes and cancer occurred frequently in the same person and at the same time. The statistics previously quoted are at least suggestive on this point. A medical journal, some years since, pointed out that:

"The discovery that malignant tumors were at times rich in glycogen also led Manders to look upon a cancer as a 'local diabetes,' curable in theory by a diastatic enzyme. Later it was shown that the glycogen in tumors was not connected with their pathogenesis and had little significance of any sort." But more re-

cently, "Hirshfeld, in the *Berliner klinische Wochenschrift*, . . . called attention to a certain relationship between diabetes and neoplasia of the female genitals, including the normal hyperplasia of the gravid uterus. The claims advanced for the existence of this association are as follows: Pregnant diabetic women show a diminished tolerance for carbohydrates, and this loss may not be regained. Tumors of the generative organs often develop at about the time of inception of diabetes, as if the former were able to influence unfavorably the carbohydrate metabolism. Cutting down the carbohydrates will sometimes diminish the degree of hemorrhage from uterine myomata. Again, extirpation of these tumors—uterine fibromyomata, ovarian cystomata—will often cause improvement in a diabetic patient. Glycosuria may disappear outright or persist to a limited degree."

It is, therefore, considered reasonable to regard this association of tumors with diabetes as not wholly foreign to the older views of Manders and others.

These observations are deserving of thoughtful consideration. There is certainly a sufficient amount of evidence to support the conclusion that hypernutrition and malignant disease more often coincide than can be explained as a matter of pure chance; while diabetes and excessive body weight are more often associated than not in cases which terminate fatally. In any event, it is extremely suggestive that the diabetic death rate of the United States Registration Area and of the city of New York should be about the highest known for any country or city at the present time.

A NOTE ON GENERAL PARESIS AT THE DANVERS STATE HOSPITAL.*

BY HARVEY M. WATKINS, M.D., HATHORNE, MASS.

The problem of syphilis is ever present. Despite the educational campaigns on venereal disease, the articles in lay and professional journals, the continual tendency toward moral and social uplift, yet we see each year the victims of neglected treatment being admitted to our institution.

The purpose of this paper is to consider briefly that class of patients, the general parietic, who was formerly thought to be a permanent invalid and hopelessly bedridden; the most that could be expected was a short remission. Their treatment consisted of custodial care, therapeutic indifference and pessimism. The end came after a long period of being bedridden, and bedsores were always conspicuous.

In this hospital from 12 to 17 per cent. of all

*Read before the Essex County (South) Medical Society, Feb. 8, 1922, at Danvers State Hospital.

admissions show evidence of syphilis in some form. Of this number over one-half show positive signs, clinically or serologically, of general paresis; the yearly average for the last five years being 55 per year.

A routine blood Wassermann is taken in every admission. If this is positive or if neurological signs or symptoms are present a lumbar puncture is done. Frequently a case is seen that has a negative blood with obscure clinical symptoms. In all such as this a lumbar puncture is also made, which is of great importance, both from a diagnostic and prognostic standpoint.

At the present time we have 54 paretics in the hospital, 40 males and 14 females. Of this number, 42 are being daily employed in some sort of work, varying in amount from one to six hours. The character of their work ranges from polishing or swabbing a floor, for an hour a day, to carrying on routine duties as a plumber, running a washing-machine in the laundry, working on farm, making cement blocks, etc.; in fact, any and all occupations around the hospital, that can be done by patients, have been done at different times by the paretic; some showing a fair amount of initiative, others requiring a large amount of supervision and several requiring constant oversight, but are able to carry on in some kind of employment.

The most interesting group at present is that group that is residing in the community. Thirteen such cases are now under our observation, 8 males and 5 females. Four of this number are returning on Monday for treatment and carrying on their former occupations the remainder of the week. Industrially and economically these present many improvements over the past. One, a mother, is caring for her home and family, with the assistance of a maid. One, a male, is doing micrometer work in a shoe factory, another cutting soles, another stitching uppers, two are engaged in farming, one works in an electrical plant, while one, a female, has been outside the institution since August, 1913. She is doing housework as a maid; has changed positions three or four times. Her present employer understands her temperament, and while at times she is somewhat irritable, requiring a visit from our outpatient department, she has been able to get along for about nine years without returning to the hospital. Some are able to continue as regularly employed while others are capable of only a few days a week. They are followed up by our Social Service Department, adjustments are made in the community, work occasionally changed, advice and counsel freely given. They are also seen at clinics and assistance given in every possible way. In this manner six have managed to remain outside for an average of four years, six months each,

thereby contributing to the support of their families, their own, and to the relief of the huge burden our State must bear in the care of its charges.

A vast amount of literature on the treatment of paresis is constantly being published, various methods of treatment devised and conflicting claims advanced for each. Elaborate technique is required for some, a thorough knowledge of surgery is desirable in others. While all of these offer advantages and disadvantages, many of them are not practical. Our idea has been that it does not matter a great deal as to the method employed as long as the patient is treated, regularly and continually, and so long as the antisiphilic remedies come into contact with the blood, the cerebrospinal fluid and their adjacent structures.

Our plan of treatment is not offered as the best, far none, but is offered as a practical, workable solution, under our present knowledge of the disease. It may be divided into specific, hydrotherapeutic, medicinal, and follow-up. Well-diluted arsphenamine solution (0.1 gm. in 30 cc.) 0.3 gm., given intravenously weekly, for a period of 6 to 8 weeks, followed by a course of mercury injections for a similar period, given intramuscularly; potassium iodide may be given for a like period. Treatment is then omitted for two weeks; then a repetition of the above course. After six months if there is evidence of improvement, clinically or serologically, the treatment is continued. If no improvement, then a question arises of further treatment. In the majority of cases it is continued, unless by reason of physical failure or severe untoward reactions, it is deemed advisable to discontinue it. Sometimes arsphenamine, *per se*, may be contraindicated and, therefore, other forms of treatment are necessary.

At times a lumbar puncture is done previous to administration, thereby better fitting the cerebrospinal fluid to absorb the arsphenamine from the blood. This is not frequently required as it is a known fact that it does reach the cerebrospinal fluid, and can be recovered there as such, thereby showing that intravenously administered it does reach the central nervous system. Hydrotherapy has been of great service, as body elimination is very desirable, and continuous baths, tonic showers and cabinet sweats are of use in quieting some of the more excited stages. Tonics are useful, laxative required, and the physical comfort of the patient should go hand in hand with any specific therapy.

As soon after admission as possible, suitable work is provided and encouragement offered by all those that come in contact with the patient; and last, but by no means least, is that part of the program carried on by our Social Service Department, whereby the patient can be placed in the community, employment found,

difficulties righted, and if not able to reside outside the hospital for a long period of time, short visits may be arranged.

For the hospital year ending September 30, 1921, there have been administered 1267 arsphenamine injections, 882 mercuries, a weekly average of 25 and 17, respectively.

It is interesting to note at this time the effect of treatment on the terminal stages. Formerly the parietic remained in bed for several weeks or months before the end came. He was a constant care, helpless, bedsores prominent, tube-feedings constantly required, untidy and cachectic. By treatment the terminal stages are shortened, the last four deaths being in bed less than three days.

In passing, it may be mentioned that all other cases of syphilis are actively treated and all Wassermanns are rendered negative before discharge, thereby trying to prevent the development of tertiary symptoms at a later date.

CONCLUSIONS.

The apparent improvement in a few cases justifies the belief that routine administration of antisyphilitic therapy is called for in all cases of paresis, and that he is a better patient, both within and without the institution, under treatment. Practically no ill effects have been observed under intensive treatment. Twenty per cent. are able to "carry on" outside by the aid of the Social Service Department and our outside clinics. Seventy-seven per cent. of those in hospital are able to do some form of useful work, while, of the sixty-seven studied, only nine are in bed, and only four of those continuously.

BRIEF ANALYSIS OF 500 CASES REFERRED TO THE BOSTON CITY HOSPITAL OUT-PATIENT HEART CLINIC.*

By BURTON E. HAMILTON, M.D., BOSTON,
AND
JOSEPH E. HALLISEY, M.D., BOSTON

A special cardiac clinic was started in the Medical Out-Patient Department of the Boston City Hospital two years ago. This paper refers to the first 500 cases sent to this clinic. Five hundred cases should represent the amount of heart disease in a community of somewhere near 25,000 souls. It seems reasonable to believe that the cases in this clinic, from the nature of the hospital, should afford a picture in miniature of heart disease in the whole community, at any rate as little distorted by artificial conditions as we can obtain offhand. We have no actual survey of a community. Surveys of heart disease in schools, the army, industrial groups, among

life insurance applicants, afford only narrow glimpses of the whole picture.

Totally disabled, bedridden cases, do not come to this clinic, so the picture presented should not be at any rate unduly gloomy.

Following is the grouping of these cases by diagnosis:

Rheumatic Heart Disease.....	202
Potential Rheumatic Heart Disease.....	45
Arteriosclerotic Heart Disease.....	26
Cardiovascular Syphilis.....	26
Congenital Heart (or Suspected Congenital Heart).....	19
No Heart Disease.....	69
Neurasthenia with Cardiovascular Symptoms.....	40
Heart Changes with Hypertension.....	19
Miscellaneous.....	54

500

Etiological classification of heart disease such as the above has been used to some slight extent for a long time; of late years its use is becoming more and more general. We have used it since the clinic started. Its advantages are obvious. It is impossible to think clearly about heart disease without some form of etiological classification.

A few of the above groups deserve comment. Following is a division of the rheumatic heart disease group into decades by ages of the patients:

Age of Patients in Decades	Number of Patients
-10.....	27
11-20.....	102
21-30.....	27
31-40.....	21
41-50.....	18
Over 50.....	7

202

We have no wish to attack so vast a subject as rheumatic heart disease in this paper, but these figures demand some discussion. One hundred twenty-nine patients under twenty, with 48 in the next two decades is remarkable. One hundred two in the second decade, and 27 in the third, suggest that few more than a score of the 102 will be alive and not disabled ten years hence. There is no reason to believe that any artificial factors have sent a disproportionate number of children and adolescents to the clinic.

More than half the cases in the decades above the second have contracted their heart disease since their twentieth year. This will counteract any possible unrecognized factors that may have sent us a disproportionate number of adolescents. Among the patients in the upper decades are some that had their heart disease in adolescence and are still far from disability. It is possible for some to live long and live well in spite of rheumatic heart disease.

Not far from one per cent. of our school children have rheumatic heart disease. In the light of the above figures this large number of chil-

*Given in part at the Boston City Hospital C. Meeting, April 14, 1922.

children in the community with rheumatic heart disease makes an unpleasant picture to contemplate.

It is generally believed from convincing personal observations (that nearly every physician dealing with rheumatic heart disease has made) that removal of tonsils and of oral sepsis has a beneficial effect in several ways on the progress of rheumatic heart disease. We have some statistics to bear this out. But many of the successful cases in this clinic have succeeded in spite of complete neglect of these matters. Many others we see pursue a rapid downward course in spite of every reasonable effort at removal of foci of infection and closure of portals of entry. We can repeatedly pair two similar cases, and under similar treatment from this point of view watch one do well and the other progress steadily to heart failure and total disability. These procedures do not offer the final answer to the problem. This is fairly generally believed, and we have again some statistics to confirm this belief.

In this clinic we are continually impressed with the probable fact that many ambulatory rheumatic heart disease cases have a low grade active infectious process at work in their hearts, and that this active infection rather than mechanical handicaps from old scars, or repeated reinfection, is what accounts for the continued downward progress of many cases many months after a rheumatic fever attack has subsided, and proper attention to teeth, tonsils, etc., been given. We know that rheumatic heart disease has active febrile stages. Nearly every one agrees that during these stages rest in bed is essential. We have endeavored in this clinic each time that we have made a diagnosis of rheumatic heart disease, to add to this, so far as we could, whether or not the disease was active at the time. We have tried to give patients whose heart disease we believed to be active, rest in bed until signs of activity ceased. Diagnosis of this activity is a very unsatisfactory task to attempt in out-patient work. The principal evidence for it is fever (often slight) without other demonstrable cause than a rheumatic heart disease. We have obtained temperature records on suspected cases by various means; such as a week in hospital, or in bed at home with daily visits by district nurses. In 49 (out of the 202) cases we have been able to make a diagnosis of active or probably active rheumatic heart disease. In some other instances we have been forced to recognize activity when it was not at first suspected, by the progress of the case in question.

It remains to be seen whether after these methods are faithfully pursued a survey of cases in this clinic a generation hence will present a less unsatisfactory picture than the present one.

Following is the number of rheumatic heart disease cases showing, so far as these diagnoses

can be made, pure aortic regurgitation, pure mitral stenosis, combined aortic regurgitation and mitral stenosis, and the number of patients under each of these headings that are over 30 years of age.

Number of patients with aortic regurgitation, 28 (of these four aged over 30); mitral stenosis, 56 (of these 23 aged over 30); aortic regurgitation and mitral stenosis, 22 (of these five aged over 30).

It is evident first that the old belief, now generally discredited, but still occasionally expressed, that aortic regurgitation is more often due to syphilis than to rheumatic diseases, is wrong. Here are fifty cases of aortic regurgitation from rheumatic heart disease, against a total of twenty-six cases of syphilitic heart disease in this open clinic.

We often hear it stated that pure aortic regurgitation is a less disabling condition than mitral stenosis. An occasional pair of cases bears this out, but in this series of rheumatic heart disease cases many more (and a higher percentage of) the mitral stenosis cases have lived long and well, than of the cases of aortic regurgitation. In general, basing prognosis in rheumatic heart disease on the site or extent of a lesion is bound, by the nature of the disease, to be unsatisfactory. This point is mentioned simply because diagnostic analysis of these cases brings it up. Experience in this clinic suggests, as is reasonable, that activity of the infection is the single most important factor in the prognosis of rheumatic heart disease.

The potential rheumatic heart disease group (patients that have, or have had, chorea or rheumatic fever without as yet having demonstrable heart disease) undoubtedly should be larger. This is a really new diagnosis, but one welcome to all familiar with rheumatic heart disease. It is in increasingly general use due to the approval of the New York Association of Cardiac Clinics and to the efforts of Dr. St. Lawrence of New York, who has showed its significance in practice. As yet it is not fully recognized that these cases are referable to a special heart clinic.

Arteriosclerotic heart disease is a very elastic diagnosis. There is no satisfactory standard as yet for its use. It is not, of course, a pathological and clinical entity. In certain cases it is, however, as clear cut clinically as, for instance, Parkinson's disease. We have tried to use this diagnosis only in cases with definite heart changes which could be accounted for only by the degenerative changes associated with age.

The groups called "No Heart Disease" and "Neurasthenic States with Cardio-vascular Symptoms" form the rejections from the clinic. These combined diagnoses should approximate 30 per cent. of the total cases referred to the clinic. For various reasons we did not keep records of many of these cases at first, but only of those that for some reason or other we wished

to re-examine. About half the total rejections might be classed as neurasthenias with some combination of the following symptoms predominating: breathlessness, weakness, tachycardia, palpitation, heart pain, giddiness, fainting, trembling, vasomotor disturbances (such as cyanosis).

No combination of these symptoms *alone* justifies diagnosis of heart disease. (A possible exception of this statement might be a convincing history of "true" angina pectoris without other symptoms. No such case has appeared in this clinic. Three diagnoses of angina pectoris have been made in these 500 cases. Two had cardiovascular syphilis, the other was classed as arteriosclerotic heart disease. Heart pain as a symptom is very common in the clinic, bearing no relation to heart disease.)

These symptoms are the ones that physicians in military service became familiar with during the world war, grouped under various names such as "Effort Syndrome," "Soldier's Heart," "Nervo-circulatory Asthenia," etc. A great amount of careful study was done on these conditions, and satisfactory methods for differentiating patients disabled by this state from those disabled by demonstrable organic disease, were evolved. Yet now we find the heart clinic, at any rate, pervaded by these patients who are without any true signs of heart disease, but nearly all of whom have been told by physicians in the community at some time or other that they had some disabling heart disease.

It is interesting to remember the attention paid in medical literature and in discussion to this class of cases three and four years ago, and the nearly total absence of such interest now. It is not suitable in this paper to go into the matter deeply, but this brief survey of 500 unselected heart cases suggests at once that there is a large group of more or less disabled individuals in our general out-patient departments that is, as a rule, wrongly diagnosed and consequently wrongly treated.

Furthermore, many of the cases listed here under diagnoses of true heart disease show in addition a complicating neurasthenia. They are often disabled by symptoms included in the above list, and not by symptoms in any sense directly due to heart disease. It is remarkable how often the death of a friend or relative of a heart patient immediately precedes this patient's increased disability from some of the above symptoms. Successful classification and treatment of (at any rate adult) heart patients depends in large part on the differentiation of disability due to heart failure from disability due to complicating fatigue symptoms resulting from social misfortune, worry, or overwork. This is self-evident, but again, the large number of heart cases in this clinic disabled by "neurasthenia" demands recognition in this analysis.

CONCLUSIONS.

From a brief survey of 500 unselected cases of heart disease it appears that:

1. Rheumatic heart disease is extraordinarily fatal, at any rate among children and adolescents. This series suggests that the great majority of adolescents with rheumatic heart disease have an expectation of life of less than a decade.
2. Forty-nine of 202 unselected rheumatic heart disease cases, under careful observation, showed more or less strong evidence of an active infectious process of the heart. Activity of rheumatic heart disease is easily overlooked.
3. Approximately 15 per cent. of cases referred to a general heart clinic have neurasthenia with symptoms suggesting heart disease. These cases usually have been diagnosed wrongly as cases of true heart disease.

LANTERN SLIDE DEMONSTRATION OF SOME POINTS OF HEART DISEASE.

BY WILLIAM D. REID, M.D., BOSTON.

ABOUT twenty slides, comprising photographs, diagrams and electrocardiograms of normal and pathological hearts were shown. They included some of the recent changes in the knowledge of cardiac physiology and other data which support the conception that the crescendo murmur ending in a sharp first sound is early systolic in time and ventricular in causation rather than presystolic and due to the contraction of the auricle. The subject does not lend itself to further presentation without reproduction of the cuts.

SOME FACTS CONCERNING DIGITALIS.*

BY THOMAS J. O'BRIEN, M.D., BOSTON.

GRANTED that we have a well-taken history, a thorough physical examination, correct interpretations of our laboratory findings, and the results of our instruments of precision; in other words, a correct diagnosis, yet our patient is not benefited unless we administer the correct treatment. Personally, I feel that the weakest link in the chain of clinical medicine is the application of correct treatment, and this is especially so in treating diseases of the heart.

Digitalis was first introduced to the medical profession by William Withering, about 1775, and while it is one of our most valuable drugs, it is, perhaps, the least understood. When we lose confidence in its action, and even when it has been said that hundreds of patients die annually, from the fact that digitalis and its

*Read at the Staff Clinical Meeting at the Boston City Hospital, April 14, 1922; also at the Annual Meeting of the Carney Hospital Alumni Association, April 26, 1922.

allies have not possessed the virtues required of them, the blame is seldom merited, being more correctly due to improper dosage, deterioration of drug, or faulty selection of treatment.

Digitalis is a perennial plant, indigenous to Western and Central Europe, and may be grown in the United States; but unless the soil contains iron or manganese, the leaves have little medicinal value. In Virginia, Wisconsin, Minnesota, and near the Rocky Mountains, are found the best products in this country, while that grown in Kentucky, which has a clay soil, is found to be worthless for medicine. American *digitalis* compares favorably with that grown in Europe, but only eight of the twenty-five specimens examined by Pratt and Morrison came up to standard of the United States Pharmacopoeia.

While *digitalis* is official in the pharmacopoeias of all lands, we find different requirements, some specifying that the leaves are to be used within a year of time of being collected; some requiring that the leaves be gathered from wild plants; and others, that the leaves be gathered while plant is beginning to bloom. In the United States Pharmacopoeia of 1890, only the leaves collected from the plants of the second year's growth were accepted as official, but the present pharmacopoeia specifies the carefully dried leaves of the *digitalis purpurea*, without the presence or admixture of more than 2 per cent. of stems, flowers, or other foreign matter. The strength of the tincture is determined by a biological assay, the minimum lethal dose being not greater than .006 mil. of tincture for each gram of body weight of frog. *Digitalis* should be preserved in tightly closed containers, protected from light.

It may interest you to know that crude drugs are not usually purchased directly from the countries where they are grown, but are sent to one of the great world-marts, at London, Hamburg or Amsterdam, where the drugs are sorted, assayed, rebaled and labeled. The buyer goes through the vast warehouses, and makes his purchases wholly from the labels or tags, and finds upon delivery here, just what the tag described, as, "excellent leaf," or, "medium quality, many stems;" or "poor grade leaf, much foreign matter," and so on, the price being influenced by the quality of the drug. Occasionally, the leaf is purchased directly from the farmer, in this country, and certain men market their products in this city, giving a very fresh and dependable leaf.

The commercial, as well as the medicinal value of a crude drug, depends upon the chemical assay of its active principles, as the amount of morphine in a sample of opium; of strychnine in *nux vomica*; and quinine in *cinchona*; but, unfortunately, the chemical analysis of *digitalis* fails to reveal the amount of active principles in an accurate manner, and the sub-

ject of a dependable method for chemical assay of this drug is in a state of chaos. It is also impossible to make a relative comparison between a chemical and a biological assay.

The active principles of *digitalis* are glucosides, which do not have the property of forming salts with acids, like the alkaloids. While some authorities agree that certain glucosides have been isolated, and identified, other investigators claim that often the same product is marketed under one name when it is sold in an amorphous form, and another name when it is sold in a crystalline form. It is generally admitted, however, that digitoxin is the most stable and most powerful glucoside, its dose being 1/480 of a grain. The other glucosides usually mentioned are digitalin, digitalein, digitophyllin and digitonin, the last being a saponin, and although inert as a medicine, is of value, in that its presence makes the other glucosides soluble in water, thus giving the tincture and infusion about the same constituents.

The importers grind the leaves into a powder, and, in cartons, it reaches the retailer, where the tincture, infusion, fluid extract, or pill, is made for the patient, as may be prescribed by the physician. Powdered *digitalis* varies from forty cents to two dollars a pound, and it is natural to suppose that the bale tagged "poor grade leaf" was the one ground up to sell for the cheapest price, and it is also within the bounds of imagination to think that this particular grade is a popular one. The United States Pharmacopoeia directs that 100 grams of powdered *digitalis* be placed in a percolator, that a menstruum of three volumes of alcohol and one volume of water be added, and that this be allowed to percolate until one liter is obtained.

Every tincture made this way is supposed to be of standard strength, and is sold as such, but investigation shows that it is rarely found to be so. While the United States Pharmacopoeia provides a biological assay, by the so-called "frog method," to determine the accuracy of the drug and its preparations, we find that there is hardly a pharmacist going to the great expense of having this assay made. A few have done so, and one, to my knowledge, found that his tincture was one and a half times as strong as the United States Pharmacopoeia's, although sold, up to that time, as officially correct.

A sample of the tincture of *digitalis*, made according to the United States Pharmacopoeia, and used at the Boston City Hospital, was sent to the Department of Pharmacology of the Harvard Medical School, in March, 1922, for a biological assay, which was made by the official "frog method," and the report shows that the preparation was "just under the pharmacopoeial strength, or, as 7 is to 6, in in-

verse ratio." The difference, although slight, shows that the tincture is somewhat weaker than it should be. At the same time, another sample of the same tincture was sent to the Division of Biological Laboratories, under the Department of Public Health, for assay, and their report reads, that the preparation was at least 25 per cent. stronger than the standard requirement for the official tincture. This assay was made by the Reed and Vanderkleed method, wherein guinea pigs are used instead of frogs. While the frog method is the official one, it is open to criticism, as the United States Pharmacopoeia does not specify the species of frog, and Pratt and Morrison¹ have found the European frog to be more susceptible to a lethal dose of digitalis than the American frog.

A well-known pharmaceutical house admits that it is obliged to spend at least five days in standardizing the frogs, to the temperature, water, etc., before testing the digitalis by the U. S. P. method of assay. Hatcher, who has done much work along these lines, has found the "cat method" to be more dependable than the others, but it is quite probable that an assay of the tincture by this method would show a still different result from the two already reported. For instance, Hatcher and Eggleston,² using the cat method, reported results of stability in infusions entirely different from that of Pomeroy and Heyl,³ who used the frog method. Hale, using the frog method, found that it took 16 times the amount of digitoxin and eight times the amount of digituratum that Hatcher and Brody⁴ required per kilo for a cat.

Another observer, Pittenger, is trying to perfect a method of biological assay which will be inexpensive, practical and accurate. His method calls for 500 cc. of tap water, a few gold fish, kept at 22° Centigrade, and the tincture to be tested. Exhaustive experiments involving the use of over 1000 fish proved the method to be most sensitive, when dilutions were used, which produced death in approximately three hours.

The amount found to be most satisfactory averaged 2.85 mil as the minimum lethal dose, and neither the size nor number of gold fish used nor the alcohol in the tincture seemed to affect the result.

With the present uncertainty of accuracy; with the lack of consistency in reports of the various methods of assay; with the marked differences in opinion, in the minds of our best authorities, as to the present official method; and with the great expense entailed, we can hardly blame the pharmacist for not having his digitalis assayed.

I know that my confrères will bear me out when I say that almost every student, and many practitioners, associate all cardiac con-

ditions with digitalis, and whatever the irregularity, the murmur or symptom, digitalis is at once prescribed.

While it is impossible to discuss the indications of digitalis in each specific case, it should be remembered that although it aids the heart to greater action, by calling on its reserve power, it cannot do the impossible, namely, increase the absolute power of the heart. Again, the dose suitable for certain conditions of heart disease, while the patient is at rest, is not a proper dose for a patient exercising or continuing at his work. The heart will do more actual work, at a slow rate, without exhausting itself, than it will with a rapid rate, which soon wears out the tired heart muscle. Thus, when digitalis is clearly indicated in a case, rest, both physical and mental, is just as surely indicated.

It is very interesting to find that tincture of digitalis is always given in drop doses, and inquiry at many drug stores indicates that 10 to 15 drops two or three times a day is the favorite manner of prescribing it. Many pharmacists dispense digitalis with a red label to impress the patient that he is taking a very powerful and poisonous medicine.

Even when you prescribe minims on your prescription you will almost always find "drops" written upon the label of the bottle, and when it is not changed, the nurse or attendant will administer drops, as they have no facilities for measuring minims.

The difference between what your patient should have taken, when you prescribed 15 minims four times a day, and what he actually did take, is startling, as proven by these vials for a day, a week and a month, showing, in multiples, that there are about two drops to a minim. This vial containing a drachm—that is, 60 minims—measures 128 drops.

The natural tendency of most practitioners is to give too small a dose of digitalis. Ten minims of the tincture has been found to measure from 19 to 25 drops, according to lip of dropper. Four c.c. of the infusion equals eight minims of the official tincture, and many a physician, who would not give 30 minims of the tincture at a dose, often prescribes a dessertspoonful or even a tablespoonful of the infusion every four hours, obtaining a satisfactory result and thus having more confidence in the infusion.

Digitalis should be given in amounts sufficient to cause therapeutic action, then continued for a while with doses capable of sustaining the effect, or omit the drug entirely, repeating dose again, if it is needed.

Deterioration of digitalis is a fact not fully appreciated by the clinician, and explains many of our failures when the diagnosis was correctly made and the treatment apparently administered correctly. Physicians naturally

assume that the authorities compel the pharmacists to follow the United States Pharmacopoeia, so wrongly feel that the preparations are always of a standard strength. This is not so. Old preparations of aconite, ergot, squill, strophanthus and digitalis have been found to be worthless by biological assay, although they were made by the official methods.

Pittenger,² who has done much work on the assay of drugs, has reported that he has made 51 assays of digitalis and that the strength of the tinctures varied from 0 per cent. to 444 per cent.

Very valuable papers on the stability of digitalis leaf extracts were published in the *American Journal of Pharmacy*, by Schmidt and Heyl in 1919 and by Pomeroy and Heyl in 1920, and their graphs and summaries are freely quoted in this article.

Rate of Deterioration of Digitalis Leaves.

Rate of Deterioration of Tinctures of Digitalis.

Rate of Deterioration of Infusions of Digitalis

These graphs show a progressive deterioration of digitalis and its preparations, which reach an equilibrium of somewhat marked stability, indicating that the leaf contains a constituent more stable than a second active but unstable constituent which is also present. Digitoxin is undoubtedly the stable and digitalin the less stable part, as proven by the percentage of digitoxin extractable, according to the opinions of these writers. Recently an observer has found traces of an organic acid which seems to be present in freshly made preparations of digitalis, but which disappears at the time our graphs show marked deterioration, probably combining to form some unidentified substance.

Pomeroy and Heyl found that infusions should be discarded in from three to five days' time, and that the addition of alcohol adds nothing to the stability of the infusion.

Assuming that the pharmacist manufactures the amount of tincture mentioned in the formula of the United States Pharmacopoeia, namely, a liter, we might expect some drug stores to have enough made at one time to last several years, and inquiry along these lines shows this to be a fact. If we have been prescribing 10 or 15 drops of tincture of digitalis, and one of these ancient, deteriorated products was dispensed on a case where digitalis was clearly indicated, we can understand our failure to get a satisfactory result.

One firm has tried to prevent the rapid deterioration by placing a certain number of freshly made tablets, of the whole leaf, in a brown glass bottle, to prevent action of the sun's rays; by placing a dehydrating agent under a layer of cotton at the bottom of the bottle, to absorb moisture, and dating the product, thus seemingly giving us a dependable tablet of the whole leaf.

The whole leaf possesses all the valuable properties of digitalis and is the best way of giving this important drug.

Most of the proprietary preparations are either standardized tinctures or are made from the glucosides, usually digitoxin, and while they have their place in medicine, as in intravenous or subcutaneous injections, they are not to be preferred to the whole leaf. Hatcher and Wilbert⁶ have compared the action and relative costs of the various proprietary preparations with that of the whole leaf, and in each case the whole leaf, or a tincture or infusion made from leaf of good quality, is preferred, although costing far less. For instance, one costly and well-advertised preparation claims to be a solution of amorphous digitoxin, but no such substance is known to science.

Fat-free tincture is found by the same observers to be a weaker preparation, containing less of the active principles of digitalis, when it is less actively emetic, than the official tinc-

ture, and the amount of fat removed is found to be so small that it could not influence the emetic action at all. The difference between the therapeutic and the toxic dose is very slight, and may produce poisonous symptoms without much warning, so it is inadvisable to repeat the maximum dose within six hours, especially by intravenous or subcutaneous methods.

Deterioration of digitalis is further emphasized by the work of E. S. Zueblin,⁷ who has experimented a great deal with a fontactoscope, an instrument constructed for the purpose of determining the amount of radio-active rays emitted by radio-active bodies. A specimen of powdered digitalis was examined on three different dates, at an interval of 323 days and again 136 days later. The sample was kept in a sealed bottle, protected from light and moisture. Marked inferiority of the drug was noticed on the second test and again on the third test. While there is no comparison between the physical radiation and the medicinal value of digitalis, it coincides with what we are trying to prove.

The proper use of a drug involves knowledge of a dose sufficient to produce therapeutic action, the rate and manner of elimination from the body, and its toxic effect. We do not know how digitalis is eliminated, as chemists fail to find it in the excreta, so we assume that it is oxidized in the body.

There is no other drug which requires such careful study in deciding upon a proper dose, as age, sex, weight and the pathological condition must all be considered, since an excessive amount will be toxic, while an insufficient amount barely supplies daily waste, thus producing no result. Pardee⁸ has found that an adult can safely eliminate 22 minims of tincture daily, and that this amount can be continued over a long period of time, thus keeping up the action desired without fear of toxic action. His work on the isolated heart shows that the whole leaf possesses properties not found in the glucosides.

A single dose of digitalis is rarely fatal in a normal individual. I cannot find a death in our records, and H. C. Wood,⁹ a toxicologist of 44 years' experience, knew of only one such case. Hauber of Munich, in 1890, reported such a death, but the fatal dose was not mentioned. That this odd drug has a cumulative effect is very well known, but when this physiological effect is produced, sufficient notice is given by the signs of heart block and by nausea and vomiting. This is due to the effect upon the central nervous system when digitalis is pushed, however slightly, beyond the maximum dose. We should remember that the earlier we recognize the indication for digitalis the more satisfactory the end-result, as

old lesions often respond poorly to the use of drugs.

The danger of single massive doses of digitalis must be appreciated, as the ventricle may lose its inhibitory action on the vagus, and the excessive stimulation of systole may cause death. Any degeneration of the myocardium is a contraindication to the use of digitalis.

There are many methods of computing the amount to give in a single dose, but they should never be given, if the patient has taken digitalis or its preparations, for at least two weeks, and it is advisable that an electrocardiogram be taken, to confirm diagnosis and check up the condition of myocardium.

It has long been thought that high temperatures of the body prevent digitalis from acting on the circulatory system, and clinicians have been warned to avoid large doses in the treatment of pneumonia, as a sudden crisis was supposed to admit absorption of an excessively large amount of digitalis, and toxic action would result. Cohn,¹⁰ at the Rockefeller Institute, feels that this is not true, and advises the use of digitalis in the febrile period of pneumonia, as a routine.

If the case is seen early, he gives half a gram on the first and second days, and again on the fifth and sixth days.

If the case is seen on the fourth day of the disease, he gives a gram, repeating a half-gram on the sixth or seventh day. His statistics certainly support his theory, but digitalis has not been given as a routine on the pneumonia service at the Boston City Hospital and we have had comparable results.

Our studies in cardiac work show that syphilis is a far more frequent offender than is commonly supposed, the Wassermann test being positive in about one-fourth of the mitral lesions, in one-half of the aortic cases, and in two-thirds of the aneurysms. While digitalis treatment is not contraindicated in a case having a positive Wassermann, antisiphilitic treatment is indicated. The symptoms of decompensation due to degeneration of myocardium by syphilis, although shown by the usual signs, have a more serious significance than those due to cardiac failure, and the use of digitalis in these cases is questionable, as the condition is due to myocardial degeneration.

SUMMARY OF PAPER GIVEN AT THE
CLINICAL MEETING OF THE HEART
SERVICE, BOSTON CITY HOSPITAL

By WILLIAM H. ROBEY, M.D., BOSTON.

ANGINA PECTORIS WITH AND WITHOUT
CARDIAC SIGNS.

DECOMPENSATION of the congestive type with oedema and cyanosis, often with previous signs of heart disease or other attacks of decompensation is quite familiar and time need not be taken to discuss it. I speak particularly to the house-officers of a type of heart failure not so commonly seen in hospital practice which has the symptom known as angina pectoris as its outstanding feature. Osler stated that in a large institution not more than one case of angina pectoris might be seen in a year while a consultant in private practice may see ten or twelve in the same time. That has been my experience. In a ten-year period in this hospital only sixteen cases are recorded. When angina pectoris occurs in a patient with evidences of arteriosclerosis, dyspnoea on moderate exertion or some form of arrhythmia, the diagnosis is often made with ease but when pain about the heart is complained of without evident cardiac or circulatory signs, the diagnosis is often difficult and sometimes impossible. In a young person without physical signs or limitation of cardiac effort, pain is often due to something else and correction of diet, habits of eating, and the bowels, will stop the pain. If aortic disease or mitral stenosis can be demonstrated, then the pain can be explained, as we know that both of these lesions may cause it. In aortic disease the pain is often about the aortic area, and in mitral stenosis about the area of cardiac impulse. It is not one of the common symptoms of these conditions.

If a middle-aged or old person complains of cardiac pain, it should always be taken seriously whether there are signs or not. The history should be most carefully studied, and, if possible, the patient should be seen during an attack of pain. If that is impossible, then a very thorough history should be obtained of how the pain comes, the area of distribution, the appearance of the face as observed by friends, the subsequent fatigue, and, in some, sweating. Sometimes in early cases the attack is induced by exertion. When it comes on after the patient has gone to bed the prognosis has always seemed to me much more serious. The physical examination should be most searching. An accentuated aortic second and a shortening of the first sound will be of greater value than the finding of a murmur. The rate and rhythm should be observed with care. While the electrocardiogram has not given any positive evidence as yet of coronary disease, the heart should be studied electrocardiographically when possible. A very mild case is now under my

observation. A man of 62 years, but looking 10 years younger who has had attacks of substernal pain localized pretty definitely at the third space and radiating to the arms and fingers; a man of good habits, without history of venereal disease and with a negative Wassermann. The pain was first noticed three years ago after climbing a small hill, and occurred at intervals following exertion for some months. It then disappeared for a year and a half and during this time the patient felt as well as ever. It occurred again a year ago, after he had carried a piece of furniture upstairs. The pain disappeared, but in the last two months it has been more or less evident after walking or going upstairs. Recently it has occurred several times just after going to bed. He has been seen twice by a competent physician, who, not finding any evidence of cardiac disease, has told him the pain is of no consequence. The physical examination of this patient is essentially negative, Wassermann negative, blood pressure 140-100. Heart is normal in size by percussion and the fluoroscope; the great vessels are normal; pulse 76; no arrhythmia, no palpable atheroma. There is an accentuation of the aortic second and a soft blowing systolic murmur. In the x-ray plates at about the third space on each side of the sternum and in the area where the patient complains of pain is an irregular hazy shadow which does not seem to be connected with the heart or great vessels, and which raises the question of the presence of a neoplasm. In view, however, of the rather long history of the case, the splendid general condition, and the lack of physical signs which one would expect to accompany a mediastinal growth, it would seem that such a diagnosis is unlikely. My belief is that this presents the pain of an early coronary sclerosis, and if the patient is careful about exertion I think his attacks may quiet down completely. There is always, however, in such a case the possibility of sudden death, as most of us know by experience.

Another example of the type of case of angina pectoris which may exist without any symptoms whatever referable to the heart is illustrated in the following history:

A man 47 years of age, whose father had died at the age of 71 of angina pectoris, gave a history of freedom from serious infections and was not aware of having contracted any venereal disease. Five years before I saw him he had a pain in the chest radiating to both arms. This condition repeated itself several times and was followed by a year and a half of complete freedom. Five months after I saw him the attacks began again following exertion of any kind, and frequently came on in the early morning after a satisfactory sleep. He had used alcohol moderately and smoked fifteen cigarettes a day. His appetite was extremely good. There was no nocturia. The attacks of pain were intense, located underneath the sternum and radiating

to the shoulders, back and arms. The attack would last sometimes for half an hour, at the end of which time the patient was utterly exhausted and covered with profuse perspiration. He had seen a number of physicians: first, a gastro-enterologist, who had put him through all of the gastro-intestinal tests, with negative findings. He was then under the care of a neurologist for several weeks, who treated him for a neuritis of the left arm. At the time I saw him the physical examination was quite negative. There were no abnormal sounds in the heart. The aortic second was not accentuated, the blood-pressure was normal, the pulse was not atheromatous. The x-ray plates of the heart showed the heart and great vessels were normal. The Wassermann test was negative. An electrocardiogram showed an inverted T wave in leads 2 and 3. The patient was kept in bed at complete rest, and was given antineuritic treatment, notwithstanding his negative Wassermann and sedatives in proper quantities to relieve pain. In spite of this, he continued to have attacks and died suddenly one month later. It is evident because of the almost complete negative findings in the heart and blood-vessels that this patient's condition had existed for several years without diagnosis, and was attributed to the stomach and nerves, but never to coronary disease.

Pain, breathlessness or easy fatigue on exertion are the three outstanding signs of a heart that may soon fail. No matter how slight the physical signs may be in a middle-aged or elderly person the onset of any of these symptoms, alone or in combination, should make the physician cautious. A colleague of mine recently examined a man's heart, pronounced it normal, and told him he might take an extensive trip. When in the far west, he collapsed, was examined electrocardiographically and found to have some form of block. He revived in the hospital, but died a few weeks later. The fact that this patient was frequently awakened in the night with attacks of breathlessness was not brought out at the original examination. We must all be very careful not to overlook important points in the history as well as in the examination.

In the treatment, rest, and sufficient study by all possible means during rest, should be carefully carried out. After rest, a study of effort tolerance should be made. Digitalis, even in the presence of a normal rate and rhythm, is a very excellent addition, provided a potent preparation of digitalis is used. Nitroglycerin, even when the pressure is not high, is often beneficial. Amyl nitrite will generally relieve acute attacks of angina pectoris. It removes the danger and dread of the pain. The diet and bowels should be carefully regulated. Worry is often as large a factor as exertion. Sleep is an important aid which is too frequently overlooked. Morphia alone or in combination with some drug such as five grains of veronal or ten grains of chloral

will frequently give a restful night. Explain to some trustworthy relative how important you think the condition is.

ORGANIZATION OF HOSPITAL AND MEDICAL SERVICES—BUFFALO.

Buffalo, N. Y., June 24, 1922.

To the Editor:

Herewith is sent an important report on the organization of the hospital and medical services of the municipality of Buffalo, prepared by Doctor Haven Emerson of New York at the request of a Citizens' Committee of Buffalo. The Department of Hospitals and Dispensaries of this city having been attacked for inefficiency and maladministration by the Mayor, a committee of 132 citizens felt it proper that a medical expert of national reputation should be called in to make an impartial survey and report.

The facts presented contain many points of general interest. The report goes beyond a mere description of conditions in Buffalo, indicating principles and methods of hospital service, and for the organization of the sources of a large community for the cure and prevention of disease. We regard this report as a contribution to standards of hospital work and the advancement of medical service through providing practising physicians with diagnostic facilities for their patients.

The Citizens' Committee, therefore, has felt that it would be of interest to the general public, and in particular to the physicians and health workers throughout the country. With this in view, an abstract has been prepared bringing out these main points, which accompanies the copy of the report herewith.

WILLIAM WARREN SMITH,
Chairman, Citizens' Committee.

White Building, Buffalo, N. Y.

The report presents the following features:

First—The practical withdrawal of the Mayor's attack.

Second—The organization of the committee and the employment of Dr. Haven Emerson to make a survey and render a report.

Third—Dr. Emerson's report is to the effect that "the Department of Hospitals and Dispensaries of Buffalo has not only emerged unscathed, but with flying colors." Then follows a brief historical sketch of the development of the present hospitals and dispensaries, showing the Buffalo City Hospital 415 beds, the Municipal Hospital 175 beds for tuberculosis and venereal diseases, the Ernst Wendt Hospital 140 beds for other communicable diseases, seven health centre dispensaries and a mental disease clinic. In addition to the facilities afforded by the Department of Hospitals and Dispensaries there is the J. N. Adam Memorial Hospital for tuberculosis 350 beds and the Erie County Hospital 300 beds. Privately controlled institutions have an aggregate capacity of 1788 beds, making a total of 3168 available for the city of Buffalo with a population of 506,775, or for Erie County with 650,000.

Standards of hospital service to the community as represented by hospital beds have been worked out by Dr. Emerson and others, and as applied to Erie County would appear as follows:

Kinds of Service.	Number of beds usually needed for 100,000 people.	Needed in Erie County (population 650,000)	Beds provided in Erie County (per 100,000).	Provided in Erie County (population 650,000).
General Medical and Surgical Care	500	3,250	334	2,169
Children	50	325	49	319
Maternity Cases	15	98	37	241
Acute Communicable	50	325	21	135
Tuberculosis	92	600	132	862
Convalescent Care (per 1,000 hospital cases)	7	7
	707	4,598	573	3,726

Even with these facilities there will be serious lack of provision for convalescent care and deficiency in the number of beds for contagious diseases. The general health programme also needs prophylactic dental care, occupational therapy in the hospitals, and nurses in the District Nursing Association who will attend confinement cases under direction of physicians.

The general arrangement and scope of work done in the hospitals at present is commended and figures are given which demonstrate efficiency. The report presents the following criticisms and suggestions:

"It would appear in Buffalo that there is lacking that spirit of professional fellowship and mutual confidence and respect which must be created and cultivated if the five medico-social professions—medicine, nursing, pharmacy, dentistry and social service—are to achieve the results the community has a right to expect, and each develop within its own special field to its full possibilities without sacrifice of the independence or adequate financial emoluments of any one of these necessarily allied professions.

"It is believed that once the public recognizes the need for adequate social service and the physicians accept this new group of associates as trusted allies, the present roughness and mistakes due to misunderstanding and insufficient support will largely disappear.

"It must be a matter of common knowledge among physicians of Buffalo as it is elsewhere that the great reduction in the incidence and deaths from preventable diseases during the past twenty years has been the main factor in altering the character of medical practice and changing the courses of income."

To meet this situation Dr. Emerson makes a number of recommendations, such as further careful study of all public and private health activities, with special reference to tuberculosis, a central association of all the hospitals for the discussion and establishment of common hos-

pital policies, and also to provide for economy through central purchasing, and finally to meet the main need there is recommended a permanent Public Health Committee. On this should be represented the medical profession, also public and private groups interested in health problems; labor, business men, and other citizens. The temporary citizens' committee under whose auspices the investigation was conducted furnishes a nucleus for such an organization. A standing committee of this kind would, it is believed, bring together the points of view of groups that now fail of mutual understanding and tend towards the permanent advancement of medical work and of the larger interests of the community in health and general welfare.

The whole report is a valuable contribution to recognized problems in hospitals and other health service to communities and could be studied to advantage by officials in very many localities.

Book Review.

A Treatise on Glaucoma. By ROBERT HENRY ELLIOTT. Oxford Medical Publications: 1922. 656 pages.

The second edition of this very excellent work now appears after four years, in a more pretentious form, a treatise instead of a textbook.

Glaucoma, it may be said, is one of the most serious problems which confront the ophthalmologist today. It forms one of the principal causes of blindness, a considerable percentage of which might well be avoided if the ophthalmologist were thoroughly conversant with and carried into practice the advances that have taken place in the knowledge of this disease. Colonel Elliott has performed a service to medicine in collecting in this book all that is known of glaucoma up to the present time. It is the best treatise which has appeared on the subject and as such it is recommended to our ophthalmologists for careful perusal and digestion. The second edition has been enlarged in all its parts. We notice many new illustrations, many additional references and an increase of over one hundred pages of subject matter. Only the more important advances can be touched upon.

The important paper of Fuchs on the anatomical variations of lamina cribrosa is noted. In the section on intra-ocular pressure and tension a large amount of new material has been incorporated, especially in regard to the systolic and diastolic pressure in the retinal artery, thus the researches of Magitot, Baillart and others are recorded, but the author rightly concludes that along this line the discussion is still in the theoretical stage and that we must "let our theory building wait on further development of

our knowledge." Nearly fifty pages have been added to the section on diagnosis.

The author's discussion of the true and false glaucomatous halos are most interesting and the measurements of this feature are valuable. The increase of pigmentation in the iris tissue as seen with the slit lamp and noted by Koeppe is mentioned, but no judgment as to its value can yet be given. There is need for a more acceptable method of measuring the corneal diameter and a new Zeiss instrument for this purpose is described. Elliott's careful consideration of the features of the glaucomatous field, the most important single sign in making the diagnosis of the disease and estimating its progress, is well done. The jagged scotomata which he describes as the Elliott sign can hardly be accepted without corroboration and must be regarded as rather fanciful. This sign suggests the cubist influence in ophthalmology. Also the improvement in the field following operation which he speaks of so constantly would seem to be overemphasized.

The writer does not endorse the previously accepted view that operation when the field is cut almost to the fixation point is likely to be followed by loss of central vision. One can hardly agree with his condemnation of the practice of permanent dilatation of the pupil in cases of central opacity of the lens on account of the dangers of rise of tension. True it is that the tension should be carefully measured before advising this procedure.

There is a good historical résumé of glaucoma operations and a handsome tribute is paid to Lagrange for his pioneer work in the development of the modern decompression operation.

The Lagrange operation is, however, hardly brought up to date and the old plates are given.

Elliott gives a detailed and thorough description of the very valuable and popular operation that bears his own name. There are valuable sections dealing with secondary glaucoma, congenital glaucoma, and the book ends with a chapter on the pathology of filtration.

review the important literature on attempts to use pancreas and pancreatic extracts in the treatment of diabetes, and describe their own method of getting active pancreatic internal secretion by (1) ligating the pancreatic duct and removing the gland ten weeks later, when the adnons tissue had degenerated, leaving the insular tissue intact; (2) the use of pancreas from fetal calves under five months, in which proteolytic enzymes had not yet developed; (3) the use of a sterile extract of whole gland prepared by a method yet to be published and one that is potent but not yet satisfactorily purified.

These were first used satisfactorily on diabetic dogs, then the purified extract was used on seven patients with marked results: a marked fall in blood sugar occurred; in two cases repeatedly examined, the respiratory quotient rose along with the return to the normal blood sugar level, indicating an increased utilization of the carbohydrate; the sugar excretion showed marked decrease, or if the dosage was adequate, disappeared; ketonuria ceased. In agreement with previous observations of others on laboratory animals, it was found that without careful control severe toxic reactions were sometimes encountered, and this will undoubtedly be a factor in the evaluation of the ultimate therapeutic utility of the method. They give tables and charts from which their deductions are drawn.

THE BLOOD CHOLESTEROL, ITS IMPORTANCE AND THE VALUE OF ITS DETERMINATION IN CANCER RESEARCH.

LUDEN, GEORGINE (*Can. Med. Assn. Jour.*, vol. xii, No. 3, March, 1922) concludes as follows: Cholesterol is an important constituent of the blood. There is evidence that the blood cholesterol plays an important part by promoting cell proliferation and combating bacterial invasion. The test for blood cholesterol is not a diagnostic one, but it furnishes valuable information concerning the efficiency of cholesterol metabolism. The activation of cholesterol metabolism after radium treatment demonstrated by the blood cholesterol determinations, and the parallel improvement of patients suffering from malignancy indicate that there is an intimate connection between disturbances, cholesterol metabolism and malignant disease. Cholesterol metabolism can also be improved by dietary measures, suggesting that beneficial effects may be expected from dietary measures tending to reduce the cholesterol intake with the food, combined with radium therapy. Since the life of the cells depends upon their blood supply, the chemical composition of the blood must be equally important; radium treatment changes the chemical composition of the blood, as is shown by blood cholesterol determinations. Spontaneous cures have been observed in well-authenticated, inoperable, "hopeless" cases of cancer; this proves that the body can wage a winning fight against malignant disease; as therapeutic measures had proved ineffective in these cases, some internal readjustment must account for the cures. Chemical investigations will solve the cancer problem by revealing the nature of this internal readjustment.

[A. W. C.]

THE NATURE AND CAUSE OF OLD-AGE ENLARGEMENT OF THE PROSTATE.

WALKER, K. M. (*British Medical Journal*, Feb. 25, 1922), discusses the cause of enlarged prostate in old men, summarizing his remarks as follows:

1. It is impossible to explain enlargement of the prostate by any theory of chronic inflammation alone.
2. Although enlargement may reproduce conditions favourable to the development of a neoplasm, the enlargement itself does not come into the category of true tumors.
3. The condition is in the nature of a fibro-epithelial degeneration, which finds its analogy in the female in sero-cystic disease of the breast.

PANCREATIC EXTRACTS IN THE TREATMENT OF DIABETES MELLITUS.

BANTING, BEST, COLLIS, CAMPBELL, and FLETCHER (*Can. Med. Assn. Jour.*, vol. xii, No. 3, March, 1922)

4. This degeneration may be regarded as an accident occurring during the progress of involution of the genital tract.

5. The cause that determines the onset of the condition is unknown, although it is not improbably connected with a loss of endocrine balance occurring during this period.

6. Prostatic enlargement shows a definite distribution that is anthropological rather than geographical in character. It very rarely occurs amongst Mongolians and Negroes.

[J. B. H.]

METABOLISM OF CHILDREN UNDERGOING OPEN-AIR TREATMENT, HELIOTHERAPY AND BALNEOTHERAPY.

HILL, L., and CAMPBELL, J. A. (*British Medical Journal*, February 25, 1922), discuss this important subject of the results of open-air treatment, sunlight treatment and bath treatment of children with particular reference to metabolism. His remarks, which are of interest and value, are summarized as follows:

1. Observations during the past summer on metabolism of children crippled with surgical tuberculosis and lying fixed in splints in bed and more or less nude, at Lord Mayor Treloar's Hospital, Hampshire, are described. Their metabolism on the average was increased 10 per cent. above the standard, for the same weight, of children confined in a closed calorimeter.

2. After three months' treatment, including graduated exposure to open air and heliotherapy, their metabolism out of doors was 20 per cent. above that in well-ventilated cubicles soon after admission.

3. Children who had been treated for many months showed high metabolism in the out-of-door conditions, those who pigmented well in the sun giving about the same figures as those who did not pigment well, after making allowance for weight. The former gave the better figures for weight.

4. It is considered that the rise in metabolism caused by heliotherapy *per se* is insignificant compared with that caused by exposure to open air. At the same time the value of heliotherapy as a factor towards arrest of the disease is not disputed.

5. Children on admission in well-ventilated cubicles gave results about 20 per cent. higher than basal standards for closed calorimeters. It is considered that the open-air conditions in the former were mainly responsible.

6. Balneotherapy increases metabolism much above the resting level.

7. The bodily tone and general condition of the children under the specially graduated treatment is remarkable when the long period of immobilization in splints in bed is considered. The treatment might be applied with advantage in other cases involving long confinement in bed.

[J. B. H.]

THE NATURE AND SIGNIFICANCE OF HEART SYMPTOMS.

MACKENZIE, J. (*British Medical Journal*, April 1st, 1922), in this paper discusses the stimuli concerned in the heart beat, summarizing his remarks as follows:

1. The stimulus for the normal rhythm of the heart arises in tissue specially evolved for the purpose. The stimulus in auricular fibrillation arises in tissue specially evolved for contraction, the stimulus production being merely an incident of the contraction.

2. There is a remarkable difference between the rhythms which arise in the conducting and contracting systems of the heart, due to the difference in the stimuli. These differences are shown especially in the response of the ventricle. The ventricular systole in the normal rhythm, as well as in those rhythms

arising in any part of the conducting system, is complete and effective.

3. The ventricular systole, when the stimulus arises in the muscle cells of the auricle, is often partial and ineffective, and when it arises in the muscle cells of the ventricle it is always ineffective.

4. When the contraction starts in the muscle cells of the auricle, as in auricular fibrillation, the stimulus which arises is much more sensitive to agents which favor or retard its passage to the ventricle.

5. The effect of digitalis is strikingly different, it having a far greater effect on auricular fibrillation and flutter and on the idioventricular rhythm than on any rhythm arising in the conducting system.

In the *British Medical Journal* of April 8th, 1922, Dr. Mackenzie takes up the reflex process and the heart beat, summarizing as follows:

1. The mechanism concerned in regulating the heart beat belongs to the vital process included under the term "reflex".

2. The cells taking part in this mechanism belong to two groups: an extrinsic, connected to the nervous system by the vagus and sympathetic nerves, and an intrinsic, which includes the sino-auricular and auriculo-ventricular nodes, and the Purkinje cells in the bundle and auricles and ventricles.

3. Agents of disease (toxins) which modify the rate and rhythm act on different parts of this mechanism, and certain disease agents produce characteristic effects.

4. Drugs that influence the rate and rhythm of the heart act in the same way, some of them also producing characteristic effects.

5. As toxins act on the same parts as drugs the effects of drugs will be modified by the effects of the toxins.

6. Before the effects of a remedy can be investigated it is necessary to know if the toxins have not already produced an effect which will interfere with the action of the remedy.

7. The kind of knowledge which disturbances of the reflex process reveals is limited to the variations in rate and rhythm, and they give no information regarding the functional efficiency of the heart.

[J. B. H.]

"PERNICIOUS ANEMIA" AND "SEPTIC ANEMIA."

HUNTER, W. (*British Medical Journal*, March 18, 1922), discusses pernicious anemia and what he calls septic anemia as an independent anemia and as a complication of pernicious anemia. He presents various illustrative cases and an elaborate bibliography. His article, however, is not particularly conclusive.

[J. B. H.]

MINOR DISPLACEMENTS OF THE UTERUS AS A CAUSE OF DISABILITY IN WOMEN.

FAIRBAIRN, J. S. (*British Medical Journal*, April 15, 1922) discusses what he calls the minor displacements of the uterus, summarizing his remarks as follows:

1. Always look beyond the mere position of the uterus and do not ascribe symptoms to retroversion.

2. In retroversion accompanying pelvic floor prolapse, subinvolution, pelvic inflammation, and tumors, the disability is due to the primary condition and not to the position of the uterus.

3. Retroversion after child-bearing with subjective symptoms of prolapse is correctly treated by replacement of the uterus and a pessary, provided the relief of fatigue is also secured and attention paid to the general health, mental and physical, and to the improvement of the abdominal and pelvic muscles.

4. If recovery does not follow after six to twelve months, operative measures will give better results than continued pessary treatment, and probably perineal repair and plastic vaginal operations will be more satisfactory than those of the hysterotype type.

[J. B. H.]

THE VALUE OF THE COMPLEMENT FIXATION TEST IN THE EXCLUSION OF ACTIVE PULMONARY TUBERCULOSIS. PUNCH, A. L., and GOSSE, A. H. (*British Medical Journal*, April 1st, 1922), present a record of twenty cases in which pulmonary tuberculosis was suspected and in which the complement fixation test was of value in proving that it was not present in any active form. They discuss this general subject and on the whole are of the opinion that this test is of distinct value in ruling out active pulmonary tuberculosis.

[J. B. H.]

PNEUMONIA NEONATORUM.

BROWNE, F. J. (*British Medical Journal*, March 25, 1922), discusses pneumonia of the newly-born infant, concluding as follows:

1. Pneumonia is a common cause of death amongst infants during the first week after birth, and accounted for 21 deaths out of 80, or 26 per cent.

2. It is sometimes due to ante-natal infection from premature rupture of the membranes, and the infant may be not only infected but also suffering from an advanced stage of pneumonia before its birth.

3. In the infant there is little defensive reaction as compared with the adult against the infecting agent.

4. Pneumonia in the first few days of life is an extremely insidious disease, generally presenting no characteristic symptoms which might lead to its presence being suspected and the carrying out of physical examination.

5. Even at *post-mortem* examination the presence of the disease may be missed if microscopic examination of the lungs is not carried out.

6. "Acute hemorrhagic pneumonia of infants" forms a distinct clinical and pathological entity which gives rise to sudden death in children who may be apparently previously healthy, either full-term or premature. It follows acute congestion of the lungs, the fragile vessels in the alveolar walls rupturing and flooding the alveoli and bronchi with blood. The sudden death is preceded by epistaxis and blanching of the skin, and the etiological factor may be organismal or possibly of the nature of an immediate anaphylactic reaction.

7. The importance of avoiding premature rupture of the membranes during labor, and of taking every precaution to safeguard the newly-born infant against infection, cannot be over-emphasized.

[J. B. H.]

STUDY IN EXPERIMENTAL RICKETS.

POWERS, G. F., ET AL. (*Johns Hopkins Hospital Bulletin*, April, 1922) contribute another article excellently illustrated on experimental rickets, summarizing their opinions as follows:

1. The object of the experiments was to determine whether or not radiations from a mercury vapor quartz lamp prevent the development of rickets in the rat.

2. A diet was employed which at room light regularly gives rise to a disease identical in its essential features with rickets as seen in the human being. The diet was high in calcium, low in phosphorus, and was insufficiently supplied with fat soluble A. In other respects it was well constituted.

3. Nineteen rats were placed on the diet. Ten were exposed to radiations from a Hanovia "Alpine" mercury vapor quartz lamp for varying periods of time daily over a period of sixty-four days. Nine rats were kept under conditions of ordinary room light as control animals.

4. One of the control animals was killed after thirty-eight days; another after fifty-eight days, and

the remaining seven after sixty-four days. All of these animals showed gross and microscopic evidences of rickets.

5. The ten rats exposed to the radiations from the mercury vapor quartz lamp were killed after sixty-four days. These animals were free from rickets, both grossly and histologically.

6. The beneficial effects of the radiations from the mercury vapor quartz lamp were not limited to the skeleton, since the condition of the rayed animals underwent a general improvement.

7. The effects of the radiations of the mercury vapor quartz lamp on the growth and calcification of the skeleton of the rat and on the animal as a whole seem to be similar to, if not identical with, those brought about by direct sunlight and by cod-liver oil.

[J. B. H.]

X-RAYS IN DERMATOLOGY.

SEMON, HENRY C. (*The Practitioner*, April, 1922) gives an interesting and practical summary of diseases of the skin which he believes will be benefited by x-ray treatment. He summarizes his remarks as follows:

"If the reader will survey the dermatological conditions that have been labelled in this article as amenable to treatment by radiotherapy, he will be struck by the extremely interesting fact that *not one of them is a dermatosis in which hyperaemia is an outstanding feature*. This negation can be balanced by an equally important affirmation, viz., that each and all of them are the result, in some measure, at least, of *active cell growth*, it may be more or less simple hypertrophy as in warts, or hypertrophy and dystrophy combined, as in psoriasis and chronic eczema.

"It thus becomes evident why diseases such as rosacea and acute lupus erythematosus are refractory, and may be seriously aggravated by x-rays. They are hyperaemic conditions, subacute in type, and only resulting in hypertrophy in exceptional cases, and after long duration.

"A consideration of these data will enable even the inexperienced to recognize the type of case which is most likely to respond favourably, and will help him to realize the limitations and contra-indications of this most potent therapeutic weapon." [J. B. H.]

SOME REMOTE EFFECTS OF TONSILLITIS.

PAVEY-SMITH, A. B. (*The Practitioner*, April, 1922), discusses the remote effects of tonsillitis and recapitulates his opinion as follows:

1. The tonsil can act as a primary focus in the production and maintenance of certain systemic diseases.

2. Its condition when infected may be so latent, its past history so blameless, and its power for evil so great, as "to deceive the very elect."

3. As soon as such a tonsil is condemned it should be removed without delay.

[J. B. H.]

ON TUBERAL MAMMARY HYPERTROPHY.

GRIG, D. M. (*Edinburgh Medical Journal*, April, 1922), discusses the subject of hypertrophy of the breasts during the age of puberty. He presents in tabular form a list of previously reported cases and discusses treatment. He believes that this condition is a disease by itself with distinctive symptoms, running a definite course, urgently necessitating definite surgical procedure.

[J. B. H.]

CHRONIC INTESTINAL STASIS.

LASE, W. A. (*The Practitioner*, May, 1922), emphasizes his already well-known theories in regard to chronic intestinal stasis and its treatment, still maintaining that operative methods are the only rational means of treatment. He admits, however, that there are many subjects in whom the condition is beginning, or is not advanced, for whom it is possible to advise a system of medical and other treatment to obviate the course of operative measures. [J. B. H.]

A METHOD OF USING TUBERCULIN.

ROBERTSON, R. (*The Practitioner*, May, 1922), is an enthusiast in the use of tuberculin for the treatment of tuberculosis of the lungs as well as in glands and bone and joint affections, invariably using a mixed bovine and human tuberculin. This article is of interest as showing how far an enthusiast along one line can blind himself to the value of other methods of treatment and to the limitations of his own particular pet method. What he says should be taken as a guide of what not to do rather than the reverse. [J. B. H.]

A NEW IMMUNIZING TUBERCULOSIS VACCINE: RESULTS OF TREATMENT.

RAW, N. (*The Practitioner*, April, 1922), reports the results of his treatment of 88 cases of tuberculosis with a new form of tuberculin. This vaccine, or tuberculin, prepared as it is from an avirulent culture, can be used with complete safety, and at any stage of the disease, and even in the advanced cases he claims to have seen great relief from night sweats and other toxic symptoms.

Nathan Raw is widely known as a tuberculin enthusiast, and as such has done valuable work. I believe it to be distinctly unfortunate, however, to emphasize in the minds of the general medical public any one method of treatment such as this. [J. B. H.]

NEW TREATMENT OF GONORRHOEAL RHEUMATISM.

ROSS, A. O. (*Edinburgh Medical Journal*, May, 1922), writes an enthusiastic report of the results of his treatment for gonorrhoeal rheumatism, consisting chiefly of the intravenous injection of a preparation known as Electrogel. He reports remarkably good results in five cases, and believes that, given as he advises, it appears to be a specific in relieving pain and reducing inflammation. Bad effects are purely ephemeral. Along with this treatment, prostatic massage and vaccine therapy will be of assistance. [J. B. H.]

THE COMPLEMENT-FIXATION REACTION IN TUBERCULOSIS.

SMITH, A. N. (*Edinburgh Medical Journal*, May, 1922), in an article continued from the previous number of the Journal, concludes as follows concerning the value of the complement-fixation reaction in tuberculosis:

1. In a clinically suspicious case, where the Wassermann is negative, a positive complement-fixation reaction is strong presumptive evidence of tuberculosis.

2. In a clinically tuberculous patient, a positive reaction denotes activity of the lesion.

3. Repeated negative reactions may be taken to

indicate either the absence of tuberculosis, or that a lesion previously active has become inactive. A single negative is of little or no value in a clinically suspicious case.

4. The reaction may be negative in far-advanced cases dying of the disease.

5. A positive reaction is most likely to be found in patients where the presence of tubercle bacilli in the sputum, or the clinical signs and symptoms render the test unnecessary for diagnosis.

6. Non-specific fixations may occur, notably where the serum gives a positive Wassermann reaction.

7. The intensity of the reaction seems to bear no relation to the patient's power of resistance or to the degree of severity of the infection. [J. B. H.]

SOME POINTS IN THE DIAGNOSIS OF LATE HEREDITARY SYPHILIS.

BEESON, R. BARKER (*Illinois Medical Journal*, Sept., 1921). There are contained in this article discussions on the various means of diagnosing late hereditary syphilis. The author differentiates three means: by general physiognomy examinations, by the Wassermann reaction, and, in doubtful cases, with negative Wassermann reactions, by the therapeutic test. The following conclusions are significant:

1. Late hereditary syphilis is a remarkably protean affair, and may simulate, as does the acquired form, any known disease.

2. There are certain stigmata, such as the Hutchinson triad, the sabre-like tibia, the matiform skull, and the peribuccal scars, which may be said to be almost pathognomonic of that disorder.

3. From the standpoint of late inherited neurosyphilis, the presence of the Argyll-Robertson pupil, as well as absence of the patellar and tendo Achillis reflexes, are of extreme importance.

4. The Wassermann reaction is a valuable aid, but should not be permitted to displace sound clinical judgment. It should be regarded as a valuable symptom when present. Its reactivation is also possessed of a certain value, but, like the Wassermann, does not possess an absolute value.

5. The therapeutic test has been and remains a tried and true friend.

SERIES ON PRACTICAL OBSERVATIONS IN SYPHILIS BEGINS.

HAGEN, H. H. (*American Journal of Syphilis*, Jan., 1922), begins the first of a series of articles on the practical observations in syphilis. The author is emphasizing in this series the practical application, with the set purpose of instructing the general practitioner who is occasionally called upon to handle syphilis. The first article consists of three sections: Introduction, Etiology and Clinical Course. The discussion is thorough and uninvolved, and gives evidence of unquestionable value to the literature on syphilis.

PAY CLINICS FOR VENEREAL DISEASE.

THOMSON, ALEC N. (*Modern Hospital*, March, 1922), says the pay clinic was established for the accommodation of those venereal-disease patients who were too poor to afford treatment by a well-qualified practitioner, and yet were economically above those who were admitted to dispensary service. At present, even though they are entitled to dispensary service, they do not want to avail themselves of what they term "mere charity."

The theory upon which the pay clinic is based is better specialized medical service within the reach

of the average individual. The need for low-cost and high-grade service is especial in the case of the venereal diseases. With proper personnel, ethical publicity, social viewpoint, public-health ideas, and modern professional procedure, a clinic can be maintained to treat those individuals who can receive treatment in neither the dispensary clinic nor from the private specialist.

The pay clinic is by no means a competitor of the private physician. Not over two per cent. of its patients could afford private treatment. Private treatment costs from \$300 to \$400 per year, whereas the pay clinic affords equivalent treatment for \$100 to \$125. This rate, which is a considerable saving for the patient on the one hand, affords the physician a reasonable compensation for his services. He gets for his clinical work \$5.00 an hour, working six hours a day, six and one-half days a week. This amounts to \$10,000 a year, full-time schedule, a net income greater than the average medical man's grand total with uncollectible bills included. He can afford to devote some hours a week upon a purely selfish basis.

From the inception of the pay clinic, it has developed along various lines in various places. Some have been affiliated with hospitals or dispensaries, such as the Boston and Brooklyn dispensaries. Others are separate entirely. It is the latter type which is growing more popular.

Group medicine frequently resolves itself, in the final analysis, into the private pay clinic. Hitherto nothing better has been offered. It can administer salvarsan for \$5.00 and compensate the administrator. This cannot be accomplished by the private physician. The business principle of reducing cost as the volume of production increases applies, with certain modifications, to medical practice.

HEMOLYZING TEST FOR DRUGS.

FEYSER (*Wien. klin. Wochs.*, March 9, 1922), from Hamburger's pediatric clinic at Graz, reports a series of experiments on hemolysis as a criterion for the infiltration formation of drugs. He finds a parallelism between hemolysis and tendency to infiltration formation, except in the case of salvarsan, and concludes that in testing new pharmacological preparations hemolysis indicates the probability of infiltration formation on subcutaneous injection. [R. M. G.]

CHRONIC BACILLARY DYSENTERY.

KLING (*Wien. klin. Wochs.*, March 16-23, 1922), in a continued article, presents a clinical study of chronic bacillary dysentery and colitis gravis, reporting 18 cases of chronic colitides. He believes these conditions due to many factors of causation combined with constitutional or accessory phenomena which depress the tendency to recovery. [R. M. G.]

SALVARSAN DERMATITIS IN ANTILUETIC TREATMENT.

KLOOR (*Wien. klin. Wochs.*, March 23-30, 1922), in a continued article, reports from Finger's skin clinic at Vienna a series of 33 cases of dermatitides following salvarsan administration. He finds these occurring predominantly in women, a result which agrees with the statistics from Köln. [R. M. G.]

BLACKWATER FEVER.

ROY (*Ind. Med. Gazette*, March, 1922) describes blackwater fever as it occurs in the Deurs, India, and

its treatment of the same. The disease is preceded by a malarial attack and generally develops in the course of one. It is frequent in the rainy season which corresponds with the malarial season of the place. The onset is with a chill, sometimes a severe one, which may be followed by others. Fever is very irregular, ranging from 98° to 104°. The urine becomes dark at the very beginning, and varies in color from port-wine to black, according to the severity of the case, being darkest at the time of a chill. The quantity of urine diminishes and micturition is frequent and uncomfortable. Jaundice is usually present, varying from slight coloring of the conjunctivae to keep icterus of the whole body. Vomiting sometimes occurs and may be very troublesome. In severe cases delirium and incontinence are not uncommon. In fatal cases, death usually comes from sudden heart failure, although death in coma occasionally occurs.

The writer gives his patients a preliminary calomel purge. The following mixtures are then used.

1. Soda Bicarb., gr. x; Soda Citrate, gr. x; Potass. Acetate, gr. x; Potass. Bicarb., gr. x; Liquor Ammon. Acetate, 5 ii; Tr. Strophanthus M v; Water, ad 5 i (one dose).

2. Extr. Cassia Beareana liq. 5 ss; Liquor Strychnine, M v; Water, ad 5 i (one dose).

These mixtures are used alternately every three or four hours, according to the severity of the case. In addition, one pint of salt solution is given by rectum every four hours. If the urine becomes very scanty, hot fomentations are applied over the kidneys. Soda water is given freely. Quinine in full doses is given if fever persists after hemolysis, and all other symptoms have subsided. Absolute rest in bed is necessary, as sudden heart failure is a very real danger. [L. D. C.]

RESECTION OF THE LUNG FOR SUPPURATIVE INFECTIONS WITH A REPORT BASED ON 31 OPERATIVE CASES IN WHICH RESECTION WAS DONE OR INTENDED.

LILLIENTHAL, HOWARD (*Annals of Surgery*, March, 1922), writes as follows:

Chronic pulmonary suppurations, wholly or partially of the bronchiectatic type, are rarely curable without the extirpation of the pathological focus.

The surgical removal of a single pulmonary lobe for chronic pus infection has a mortality of about 12 per cent. The danger is much greater when more than one lobe is infected, or in the presence of other complications.

Remissions of weeks or even months may occur spontaneously.

Palliative operations may be followed by improvement, rarely by apparent cures.

The commonest cause of the disease is infection due to the aspiration of infected material during tonsillectomy.

Radiant operation should not be undertaken short of several months after the onset unless the disease is obviously spreading. The proper type of operation should be determined only on full exposure by thoracotomy. [E. H. R.]

THE PATHOLOGY OF LUNG SUPURATION.

ASCHNER, P. W. (*Annals of Surgery*, March, 1922), states that lung suppurations may be divided into:

1. Bronchiectasis, a general disease of the bronchi in one or more lobes.
2. Bronchiectatic abscess, a localized suppurative process in the course of a bronchus, and thus far observed only in post-tonsillectomy cases.
3. Suppurative pneumonitis, a diffuse purulent process.

4. Extrabronchial abscess, a localized purulent process.

Also, that certain interesting histological changes have been observed:

1. Metaplasia in bronchial epithelium.
2. Epithelial lining of bronchiectatic abscess and some smaller abscesses of Group 3.
3. Proliferation of smaller bronchioles and air passages resembling proliferation of the bile passages in portal cirrhosis. [E. H. R.]

ACUTE PERFORATED ULCER OF THE STOMACH, OR DUODENUM.

STEWART, G. D., and BARBER, W. H. (*Annals of Surgery*, March, 1922). The report made by these authors is based upon 24 acute perforated ulcers of the stomach and duodenum coming under the department of surgery during the last five years. All were given a chance of operative recovery, and with the single exception of one three-day and one two-day perforations, all survived. The operative procedure in each instance was inversion and drainage with or without plication and omental grafting. Gastro-enterostomy has not to date appeared indicated in the subsequent courses of these patients. The rationale of inversion appears further borne out by a study of the surgical pathology of perforation in the normal stomach. [E. H. R.]

POTENTIAL MALIGNANCY IN EXSTROPHY OF THE BLADDER.

SCHOLL, ALBERT J. (*Annals of Surgery*, March, 1922). presents an article based on nine cases at the Mayo Clinic and reviews the subject adequately, and makes the following statements in conclusion:

Exstrophied bladders that are subject to constant irritation and trauma have an extensive glandular covering, the result either of metaplasia from the normal covering or of hyperplasia of glands in the mucosa. Such glandular structure often shows characteristics approximating malignancy. In nine cases of exstrophied bladder, in which material for histologic study was available, two were definitely malignant, and two showed atypical cellular formation varying markedly from the normal. In the reported cases of malignancy of exstrophied bladders, which are relatively frequent, the growths were adenocarcinomas. This glandular malignancy is the type that would develop from irritation and hyperplasia of glandular structures. [E. H. R.]

REACTION OF THE BLOOD IN RELATION TO DYSPNEA.

FRASER, ROSS, and FREYER (*Quarterly Journal of Medicine*, April, 1922), made observations on the hydrogen ion concentration of arterial and venous blood, in health, and in patients suffering from cardiac insufficiency and uremia. They used a modification of the dialysis method of Levy, Rountree, and Marriott.

In healthy subjects they obtained figures for P.H. closely approximating to 7.68, with little variation between arterial and venous blood. In all of seven cases of valvular heart disease with severe decompensation they found an alkalemia (alkalosis), the highest P.H. found being 7.95; there was no relation between the P. H. and the degree of dyspnea. This is in striking contrast to the acidosis frequently found by them and by previous observers in chronic nephritis; their lowest figure was 7.37. In two of their cases of uremia a marked acidosis was found in the absence of dyspnea.

It is evident, therefore, that the reaction of the

blood is not the only, nor even the principal factor, in the production of dyspnea. [W. T.]

SYPHILIS OF THE STOMACH.

McNEE, J. W. (*Quarterly Journal of Medicine*, April, 1922), reports a case of gummatous ulceration of the stomach which is unique in that spirochetes were demonstrated in the lesion. The occurrence of gumma in the stomach, while well established by clinical evidence, has been regarded with scepticism by some pathologists. McNeer has removed the last doubt by demonstrating the treponema pallidum in large numbers in the lesion.

The chief importance of gastric gumma lies in its close resemblance to carcinoma. All of the reported cases have shown (1) a palpable tumor, (2) cachexia and (3) achlorhydria. The frequency of perforation is noteworthy, and is explained by the extensive necrosis which is met with in the active stages of the process. The histology is similar to that of tertiary lesions elsewhere, the active stages showing large amounts of granulation tissue infiltrated with round cells and with a marked tendency to necrosis, and no signs of arterial disease, while the stage of repair is characterized by the formation of scar tissue and by endarteritis. No giant cells were encountered. A review of the literature is given. [W. T.]

PATHOGENESIS OF CIRRHOSIS OF THE LIVER.

CHVOSTEK (*Wien. klin. Woch.*, April 27-May 4, 1922), in a continued article, discussing the pathogenesis of cirrhosis of the liver, concludes that this condition occurs only in persons with a connective tissue diathesis, in whom degeneration stigmata are found as tokens of abnormal developmental processes. [R. M. G.]

UROCHROMOGEN EXCRETION IN GYNECOLOGY.

KLAFTEN (*Wien. klin. Woch.*, May 11, 1922), in an exhaustive chemical and clinical study from Pebam's Gynecology Clinic in Vienna, concludes that there is no specificity of the urochromogen excretion in diseases of women, but that this reaction is of value in chronic and general conditions rather than in acute infections. [R. M. G.]

ARSENIC.

FULMANN (*Wien. klin. Woch.*, May 18-25, June 1, 1922), in a continued article, discusses extensively the action of arsenic, arsenic habitation, and arsenic poisoning, with especial reference to the various therapeutic methods of administration. He does not, however, mention the selective toxic effect of arsenic on the optic nerve. [R. M. G.]

RESIDUAL LACTATION AGONI IN THE FEMALE BREAST.—THIR RELATION TO CHRONIC CYSTIC MASTITIS AND MALIGNANT DISEASE.

McFARLAND, J. (*Archives of Surgery*, July, 1922), presents a 64-page article on this much-discussed subject. Each page contains an excellent microphotograph of specimens under discussion. The article is of interest and value. The following conclusions are reached:

1. The breasts of young virgins are composed of a stroma of pure fibrillar tissue which shows an increasing mucinoid transformation with increase of

years. Into the stroma, adipose tissue begins to find its way toward middle life, increasing until in old age the stroma is largely fatty. The parenchyma of the virgin breast always contains many cannulated ducts. It may be without lobules, may contain only rudimentary lobules, or may contain well developed lobules in rare cases.

2. The mammary lobule develops in response to stimuli that may be either local or general. Pregnancy is its chief source, and it seems to be only under its influence that full lactation hypertrophy is reached. The lobules arise through budding from the ducts as determined by the stimuli. At any stage of development, the disappearance of the stimulus is followed by retrogression or involution of the lobule, whether throughout the breast or locally.

3. The lobules constituting the parenchyma of the breast in different pregnancies are not necessarily the same. There is some reason to suppose that for each pregnancy there is a different crop of lobules.

4. Involution, the atrophy of the no longer needed lobules is a complicated process whose details vary in different individuals, in the different breasts of the same individual, and in different parts of the same breast, according to local and general conditions.

5. One of the most important sources of the modification of involution is retention of secretion. Its effect is in proportion to its extent and distribution, and is without regularity.

6. Its most striking result is the appearance of residual lactation acini.

7. Residual lactation acini are harmless decadent structures having no significance in respect to the subsequent appearance of malignant disease.

8. The accumulated cellular and amorphous debris resulting from involution sometimes obstructs the outlets of the ducts and acini, leading to retention of secretion and exudation of fluid with cyst formation. The cysts may result from dilatation of either the ducts or the residual lactation acini.

9. The cysts may be a size varying from that of a pin-head to a hen's egg, and may be single or multiple, uniformly disseminated, or collected in groups. They usually have smooth walls and clear serous contents.

10. The pressure exerted on the surrounding tissue by the growing cyst gives rise to sensory disturbances that vary in intensity according to the firmness or softness of the stroma. In a breast with stroma largely mucinoid or adipose, they may occasion no symptoms.

11. The cysts are benign and harmless. If they become large their excision may be indicated to make the patient more comfortable.

12. Cancer cysts are not specific entities. They are the result of the accidental coexistence of cysts and cancer in the same breast. Original contiguity followed by increase in the size of each determines final continuity.

13. The so-called chronic cystic mastitis is not inflammatory, and is not a pathologic entity; it is nothing but a result—or, at most, a perversion of involution.

14. It would, therefore, be desirable to abandon the term, and call the condition "cystic disturbance of the breast," or if it seems better to retain one of the older designations, that of Warren—"abnormal involution"—is probably least objectionable. The only difficulty lies in clearly defining when the process of involution can be said to become abnormal, when it is so diversified.

15. The term "adenoma" should be used only when speaking of the encapsulated tumors of the breast. Parenchymatous increases of unencapsulated or diffused form are hypertrophies, and not related to tumors.

16. There is no "cyst adenoma" of Schimmelbusch.

The term is objectionable because it makes it appear as though a tumor existed where no tumor is. The appearance on which the name depends is the result of involution to which the name residual lactation acini has here been given, and which can easily be found in one fourth of all breasts that have lactated.

[E. H. R.]

THE PROPER TREATMENT OF CHRONIC MALIGN DISEASES OF THE SUPERFICIAL LYMPH GLANDS.

YATES, JOHN L. (*Archives of Surgery*, July, 1922), goes into a rather lengthy discussion of this condition and presents an article profusely illustrated with excellent drawings of the very radical technic of complete excision of all of the superficial lymph nodes of the body, i.e., neck, axilla and groin. He believes that the removal of such areas is an advance in the treatment of this disease and presents the following summary:

There are good reasons for the universal dissatisfaction with the results of present methods of treating malign diseases. Failures are partially attributable to late diagnosis and delayed treatment; but they are also due to a concentration of medical activities upon signs and symptoms of disease rather than upon the real factor that determines the outcome—the defensive capacity of the individual.

Progress is impeded at the present time by too great expectation from the searches and researches devoted to the discovery of "cures." A very natural and human desire for a panacea may one day be gratified, but, judging from the past, that day is still remote. Meanwhile the clinicians who are treating patients must make advances with the means at hand if they recognize their responsibilities and their opportunities. There is ample reason to believe that individuals vary in susceptibility to malign diseases and also in susceptibility to their ravages once they are established. Treating malignant diseases has accomplished relatively little. Treating the patient to decrease susceptibility has accomplished a great deal in tuberculosis and can be extended to other malign affections with but one risk—that of benefit.

A logical method might well be made to combine all that is known to be effective in the treatment of disease with all that is known to be beneficial in treating the individual. Such therapy could be called scientific, and no other. If it is to be adopted, we will have to stop drugging ourselves with statistics because scientific treatment can no more be determined by statistics than it can be instituted for them. Figures compiled today upon what seem to be facts, tomorrow have little foundation in fact. Results are proof; and when favorable results are obtainable, figures are no longer manipulated to establish that fact.

In combating disease that can persist throughout a patient's life and probably does so persist, it is manifest folly to speak of surgical cures or cures of any kind. The term "cure" implies permanency, and when used in this way it is doubly harmful. It releases patients from their obligation to take care of themselves and absolves their physicians from their lasting responsibility in what has become preventive therapy. Deaths due to avoidable mistakes in treatment are no less unfortunate whether they occur in ten days or in ten years.

[E. H. R.]

(Ed. Note.—This procedure might seem reasonable were it not for the well-known fact that this particular disease under discussion is just as liable to have an extensive involvement of the deeper glands of the body as well as the more accessible superficial ones. Therefore, it is hard to understand how the removal of the superficial lesions should in any way affect the course of the disease.)

THE BOSTON Medical and Surgical Journal

Established in 1828

Published by The Massachusetts Medical Society under the jurisdiction of the following-named committee:

For three years WILLIAM H. ROBEY, JR., M.D.
ROGER L. LEE, M.D.
ROBERT B. OSGOOD, M.D.
For two years JAMES S. STONE, M.D.
HORACE D. ARNOLD, M.D.
CHANNING FROTHINGHAM, M.D.
For one year HOMER GAGE, M.D., *Chairman*,

SUBSCRIPTION TERMS: \$6.00 per year in advance, postage paid for the United States, \$7.50 per year for all foreign countries belonging to the Postal Union.

Material for early publication should be received not later than noon on Saturday. Orders for reprints must be sent to the printer with galley proof of paper. Upon written request, authors will be furnished free one hundred eight-page reprints, without covers, or the equivalent in pages in articles of greater length. The Journal does not hold itself responsible for statements made by any contributor.

Communications should be addressed to The Boston Medical and Surgical Journal, 136 Massachusetts Ave., Boston, Mass.

THE SHRINERS' HOSPITALS FOR CRIPPLED CHILDREN.

THE Ancient Arabic Order Nobles of the Mystic Shrine, the playground of Masonry, has assumed a most interesting and important medical and social responsibility. This responsibility is the rehabilitation of the needy crippled child. The membership of the order in the United States, Canada and Mexico is very large and is under one jurisdiction. The annual conventions are attended by thousands upon thousands and are marvelous and surprisingly elaborate displays. Partly hidden by their play, a very keen social consciousness has been revealed. They are convinced for the moment that the needy crippled child most merits their help.

To this end they have levied a regular annual assessment upon every member, which produces an income of considerably over a million dollars a year. They have appointed a board of seven trustees, made up of men of large business, political and professional experience, and have given them complete power to expend this large annual income. This board of trustees has decided to build forty 50-bed modern hospitals in those sections of the United States and Canada where the need of service to the crippled child is most acute. The trustees have appointed an advisory board of five orthopaedic surgeons to assist them in working out their medical prob-

lems. To this advisory board they have delegated the authority to nominate the chief surgeons of these hospitals. They have agreed to give these chief surgeons generous salaries for half-time work, and almost complete authority over the professional management of these hospitals. They desire to make these hospitals teaching hospitals with every facility for the highest grade of surgical and research work. There is to be no racial or religious distinction as to the type of patients to be admitted.

Four hospitals are at present under active construction, one at St. Louis, whose chief surgeon is to be Dr. Nathaniel Allison, Dean of Washington University Medical School; one at San Francisco, whose chief surgeon is to be Dr. Walter I. Baldwin, head of the Department of Orthopaedic Surgery in the University of California Medical School; one in the Twin Cities of Minneapolis and St. Paul, whose chief surgeon is to be Dr. Wallace H. Cole; and one at Shreveport, La., whose chief surgeon is to be Dr. Guy A. Caldwell. Other hospitals have been authorized in Canada, Virginia, Oregon, Pennsylvania, and the New England States.

This far-reaching endeavor surely offers a great opportunity to orthopaedic surgery, but more important than this, is the stirring fact that a great body of men have accepted a continental responsibility. They have distributed the financial load so that it becomes an insignificant personal burden which, when thus assumed, swells into a splendid grand total. If this fund be wisely administered, there is possibility of great accomplishment. The widespread participation is the secret of its success and the earnest of its permanence. Other foundations may yield for the time being more money, but they lack the broad stimulation for service which this movement has furnished to the members of the order and may well engender among other great groups. We are aware of no more significant charitable movement which has occurred in our national life.

ACTIVITIES OF THE LIFE EXTENSION INSTITUTE.

THE annual report of the Life Extension Institute, Inc., issued by the President as a letter to the Hygiene Reference Board of the Institute, shows a continued increase in the activities of the organization.

Three phases of its work are particularly noteworthy. The Institute has made an effort to secure contracts from Life Insurance Companies for the annual examination of their policy-holders. Seven companies have already entered into such contracts. The Metropolitan Life Insurance Company, in a statistical study of cases examined, found a reduction in mortality of 28 per cent. among the policy-holders, examined by the Institute in 1914 and 1915, and

a reduction of 67 per cent. in the mortality of those found to be impaired.

Investigations conducted by members of the Institute have been presented in "Health Building and Life Extension; a discussion of the means by which the Health Span, the Work Span, and the Life Span of Man, can be extended," by Eugene Lyman Fisk. Dr. Fisk has also prepared a volume for the "American Viewpoint" Series, adapted to readers of seventh grade intelligence.

The New York office of the Institute now has a staff of about thirty physicians, whole time and part time, and 120 technicians and lay employees. The Institute has not practiced medicine, but has referred its examinees to their family physicians for treatment, which would represent fees amounting to between five and ten millions of dollars. Plans are nearly completed for turning over as a free gift the common stock of the Institute to several leading universities, so that ultimately the control of the Institute will be in the hands of the trustees of these universities.

NEWS ITEMS.

WORCESTER NORTH DISTRICT MEDICAL SOCIETY.—By invitation, the first quarterly meeting was held at the Henry Heywood Memorial Hospital, Gardner, July 25, at 4 p. m. The speakers were: Dr. Richard H. Miller of Boston, "Errors in Diagnoses;" ten-minute papers, Dr. J. G. Henry of Winchendon, "Problems of a Country Hospital," and Dr. T. R. Donovan of Fitchburg, "Intraspinal Pressure." After luncheon there was a tour of the hospital.

DR. FRANCIS PIERCE SILVA, a well-known physician of Charlestown, died suddenly of heart disease and the effect of the excessive heat in the Haymarket Square subway station, July 13, at the age of 55. Dr. Silva was a graduate of Harvard Medical School in the class of 1893. He was a fellow of the Massachusetts Medical Society, a member of the Charlestown Medical Society and of the Massachusetts Catholic Order of Foresters and the Ancient Order of United Workmen. He is survived by his widow and a daughter.

JOSEPH BENEDICT LYONS, M.D., a fellow of the Massachusetts Medical Society, died at his home in Charlestown, July 18, at the age of 51. He was born in Charlestown on November 4, 1870, and was graduated from the Harvard Grammar School in 1885 and from the English High School in 1888. In 1894 he received the degree of M.D. from the Harvard Medical School. For two years he was house surgeon at the Carney Hospital and then started practice in Charlestown. For many years he was presi-

dent of St. Vincent de Paul Society of St. Mary's Church and was also a member of the Knights of Columbus, Guild of St. Luke, Catholic Alumni Sodality, Charlestown Medical Society, Boston School Physicians' Association, Carney Hospital Alumni Association, Boston City Club, Harvard Alumni Association and the Harvard Club of Boston, and was examining physician of the Boston Consumptives' Hospital. Dr. Lyons served as overseer of the public welfare under Mayor Peters, but resigned on account of ill health. He is survived by his wife and seven children.

DR. CHARLES I. GRANSTEIN SENTENCED.—On July 15 Dr. Charles I. Granstein of Brockton was sentenced to serve a term of from five to seven years in State Prison. About a year ago the Board of Registration in Medicine revoked the registration of Dr. Granstein, the charge preferred being "criminal assault and the performing of a criminal abortion." The court sentence was the result of conviction on the charge of criminal assault. The charge of performing a criminal abortion was placed on file.

APPOINTMENT OF DR. WILLIAM C. WOODWARD.—Dr. Woodward has been appointed executive secretary of the Bureau of Legal Medicine and Legislation, the body which will be under the control of the Board of Trustees of the American Medical Association. The functions of this bureau are set forth as follows: (1) To keep in touch with federal and state legislation relating to medicine and public health; (2) promptly and intelligently to advise interested state associations and component societies concerning medical legislation and, so far as practicable, to co-operate with them in such proper action as they may take; (3) to study the circumstances under which threatened actions for malpractice arise, with a view to devising methods, if possible, of reducing the frequency of such actions; of rendering defence—or compromise, if that be indicated—more equitable and effective; and of procuring relief and redress in actions inaugurated and carried on without probable cause; (4) to study and advise generally with respect to legal and legislative matters of concern to the science of medicine and to the medical profession.

CONGRESS OF HYGIENE IN 1923.—A Congress of Hygiene will be held in Strassburg, Alsace-Lorraine, France, in the spring of 1923. The congress is being promoted by some of the best people in France, and is being organized directly by Dr. Borrel, professor of hygiene at the University of Strassburg and director of the institute there. Dr. Borrel will be pleased to receive information concerning exhibits, either commercial or otherwise, from physicians, dealers in medical and health supplies, associations and institutions, and other agencies. Those

wishing to exhibit at the congress may communicate directly with Dr. Borrel or through the National Tuberculosis Association.

A DEMONSTRATION clinical meeting was held at the Beverly Hospital, Tuesday, June 18, at 4 P. M. The following interesting cases were shown and discussed:

Epithelioma of lip, scirrhous carcinoma of left breast, carcinoma of breast, carcinoma of right breast, question of cholelithiasis, pyelitis, ovarian cyst with twisted pedicle, ruptured appendix with abscess, cholelithiasis, pregnancy, also chronic appendicitis, fractured pelvis, ruptured bladder, contusion of abdominal wall, epiphyseal separation of symphysis pubis, emphysema of right chest.

DR. CAROLINE ELIZA HASTINGS died July 10, 1922, at the Massachusetts Homeopathic Hospital in her eighty-second year. One of the pioneers among women in her chosen profession, Dr. Hastings had become one of the best known women physicians in Greater Boston. For many years she had lived in retirement in Sharon.

She was born in Barre and received her early education in the public schools of that town, after which she entered Mt. Holyoke Seminary. She received her medical training at the New England Female Medical College, where she was graduated in 1868.

She was for seven years a professor in the Boston University School of Medicine. She had also delivered many lectures on medical subjects.

In addition to practising medicine she had been active in various community interests and served as a member of the Boston School Committee for several years. She was a woman of strong convictions and was ready at all times to defend them, especially so as a member of the textbook committee of the school board. She was an advocate of greater cleanliness in the care of the school buildings and was one of the earliest to urge that luncheons be provided for high school pupils.

She was active in the administration of the affairs of the Talitha Cumi Home, which is now conducted at Forest Hills, and to the interests of which she long had devoted herself.

WORCESTER DISTRICT MEDICAL SOCIETY.—Announcement has been made of the engagement of Dr. Charles B. Stevens and Mrs. Elena Searle Farnsworth, both of Worcester. The wedding will take place July 31, 1922. Dr. Stevens is one of the leading physicians of Worcester and Chief of the Staff at Belmont Hospital.

DR. JOHN C. BERRY is recovering from a fracture of the lower third of the right fibula.

DR. CHARLES A. SPARROW has been elected clerk and treasurer of the Medical Milk Com-

mission of Worcester, in place of Dr. Ray W. Greene, resigned. The commission has secured a moving picture film entitled "A Mother by Proxy," which is being shown in the moving picture theatres of the city as a part of their educational propaganda for "certified milk."

Miscellany.

INSTRUCTIVE DISTRICT NURSING ASSOCIATION.

JUNE THE HEALTHIEST MONTH THIS YEAR, DESPITE DAMPNESS AND HEAT.

There was a big drop in the number of new patients admitted during the month of June, a drop which had been expected in May, but which did not occur at that time and which makes June the lightest month of the year.

The decrease was principally in the respiratory diseases, there being only 26 new cases of pneumonia, 30 of bronchitis and 40 of other respiratory diseases.

The diseases of the digestive system, which usually increase with the summer months, reversed their custom this year and dropped to fewer than in May, only 89 new cases being admitted.

Communicable Diseases of Childhood.—There were 126 new cases of measles, fewer than those of last month, but an increase over those of last June. There was also a slight increase in chicken-pox and mumps.

Cancer and Diseases of the Heart.—Cancer and diseases of the heart kept up their recent record, new cases of both showing slight increases over those of last month and last year.

Visits.—Despite the fewer new cases, the work was heavier than that in June a year ago, because of the number of cases carried over from last month. There were 25,026 visits made—2281 more than in June, 1921.

Baby and Child Health Follow-Up.—There was a good increase in the well-baby visits, and the follow-up work, for the Child Health Clinic was unusually active.

RED CROSS CEASES WORK IN EUROPE.

THE relief operations of the American Red Cross in Europe were officially closed June 30. Thus closes what has been perhaps the most magnificent demonstration of humanitarian effort ever witnessed. Especially in the field of child welfare have American objectives and American methods served the world. The activities involved have given our own workers a broader outlook and better organization. The whole story is one of real achievement.—*The Nation's Health*.

STATE PUBLICITY DIRECTOR EMPLOYED.

Mr. JOHN RITCHIE has been employed as part-time publicity director for the Massachusetts Tuberculosis League. In addition to his many other activities in public life Mr. Ritchie was for years Health Commissioner of Boston and later editor of the *American Journal of Public Health*. For the past year Mr. Ritchie has been employed as part-time publicity director for the Boston Tuberculosis Association, which position he continues to hold. Mr. Ritchie will be available to any local association in the state for advice regarding its publicity work.

SUMMER CAMPS.

THE BOSTON PREVENTORIUM is now operating with twenty children; Malden has held a carnation sale which netted them \$1500 for their summer health camp; and the Hampden County Association is planning to handle 200 children at its Springfield camp this summer.

THE BLIND CHILD.

THE National Committee for the Prevention of Blindness has published a summary of state laws and rulings relating to the prevention of blindness due to babies' sore eyes.

Forty-four states require that babies' sore eyes must be reported. The only states which have made no legal requirement, relating to the reporting of babies' sore eyes, are Arizona, Nevada, Texas, and Wyoming. Physicians and midwives, in twenty-four states, are required to use prophylactic "drops" in the eyes of infants at birth. In two states, only physicians are required to follow this procedure. Two states require midwives and attendants to apply the "drops." Twenty-eight states furnish free prophylactic outfits, and educational literature relating to ophthalmia neonatorum is distributed by thirty-five state health departments.

There is a growing demand for teachers for sight-saving classes. To meet this demand a course for such teachers is being given at Columbia University under the direction of Robert B. Irwin of Cleveland. Miss Gertrude Thompson, formerly teacher of the sight-saving class of Worcester, Mass., will conduct some of the exercises.

INFESTED IMMIGRANTS.

BETWEEN April and August, 1921, 136,307 immigrants and travellers were examined at the Port of New York. There were 1,410 persons found to be infested with body lice. All were deloused and their luggage sterilized before being permitted to leave the supervision of the health department.

FINANCIAL VALUE OF HEALTH WORK.

THE New York City Health Department claims that by its many activities there is secured a saving of \$100,000,000 per year or a profit of 2,000 per cent. on the money appropriated for this department.

THE OMISSION OF OPIUM IN TREATING TUBERCULOSIS.

For three years no narcotic drug has been administered to patients in the Chicago Municipal Tuberculosis Sanitarium. More than a thousand patients are treated each year in this institution. It is claimed that the symptoms formerly treated by the use of narcotics can be treated equally well or perhaps better "by non-medicinal therapeutics, such as hot packs, hot baths, massage, fixation, adhesive plasters, dietetics, psychotherapy, heliotherapy, etc."

Correspondence.

ATTITUDE OF A. M. A. TOWARD THE RED CROSS ENDORSED.

Mr. Editor:

At a meeting of the Franklin District Medical Society held in Greenfield, July 11, it was voted to endorse the stand taken by the American Medical Association in its attitude toward the Red Cross, and also to endorse the article by Dr. Curtis in the JOURNAL for June 29, 1922.

CHAS. MOLINE,
Secretary Franklin District.

OLD NUMBERS OF THE ARCHIVES OF INTERNAL MEDICINE.

Mr. Editor:

I know of an institution which would appreciate old numbers of the *Archives of Internal Medicine*. All of my own I have given to the Harvard Medical School for use as duplicates, and I now learn that there has been a great demand for these by other institutions throughout the country. In seeking for past volumes of this journal, to my horror I learned from one of my friends that he had thrown his old numbers into the waste basket! This prompts me to ask anyone who chances to have old numbers of the *Archives* which he is not using, if he would be willing to part with them for an institution which would utilize them to advantage, and also to call to the attention of physicians in general the desirability of giving all old medical books and journals to medical libraries. Dr. Farlow for a long time has sought these for the Boston Medical Library, and at the Harvard Medical School, too, these would be much appreciated. These old volumes, if not directly utilizable by the library, are exchanged with the greatest possible advantage for other periodicals and books.

I hope, therefore, that any of your readers who chance to have old medical books or other matters of medical interest will not forget the Library of the Harvard Medical School as well as the Boston Medical Library.

Very truly yours,

ELLIOTT P. JOSLIN,
Chairman Committee on Library,
Harvard Medical School.

THE AMERICAN MEDICAL ASSOCIATION OF VIENNA.

June 30, 1922.

Mr. Editor:

The American Medical Association of Vienna wishes to have you announce through the columns of your journal, the restoration of friendly understandings between their organization and the teaching body of the University of Vienna.

A Special Committee, elected by the Association, after a thorough investigation of the charges of discrimination against Americans, which were reported by members of our Association and published in our recent memorandum to your Journal, find that the men who made the accusations of discrimination were either unable or unwilling to substantiate these charges under oath. Further, the courses in question were not so called book courses and consequently were not under the control of the A. M. A. of Vienna.

It is the sentiment of this Association, that the men of the teaching body of the University of Vienna have suffered by this unjust criticism.

We further wish to state, that through the efforts of our Special Committee, working with a like Committee from the teaching body, sufficient numbers of book courses in English in all branches may be had at prices of from \$3.00 to \$5.00 per hour for the group, taking such courses.

We are very glad to announce this return of friendly relations between the teaching body and our Association and hope that this communication will be given the same publicity as was given our former memorandum.

JOHN J. GEIZ,
B. KAUFMAN,
WM. WILSON.

DIVISION OF MENTAL HYGIENE.

July 15, 1922.

Mr. Editor:

I note on page 36 of our July 6, 1922, issue, over the signature of James S. Stone, Secretary of the Committee on State and National Legislation, that the said Committee reports that "The plan to establish a Division of Mental Hygiene within the Department (of Mental Disease) has been put off."

This is not correct. A law was passed and signed by Governor Cox and I have the quill with which he signed it, which establishes a Division of Mental Hygiene within the Department of Mental Disease, with a Director whose duties are clearly outlined. It is a most progressive measure and is going to be far reaching in the carrying out of a programme for prevention of mental breakdowns.

This Committee also reports: "The plan to have those indicted for crime of a capital nature or indicted more than once for crime, examined by the Department of Mental Disease to determine their mental condition, was defeated."

This is also not correct. For I also have the quill which signed the above bill on May 20, 1921—and it has been a law for a year, and a most successful law. Wickersham of New York is quoted as saying, "This is one of the most progressive laws passed by any State in years." This year an attempt was made to perfect the reporting by the clerks of the courts of the cases covered by this law, but it was defeated by three votes, as the result of John P. Manning, Clerk of the Superior Court, Suffolk County, circulating the Legislature at the last moment, objecting to the Probation Officers being directed to report the records of the men to the clerks of the courts. So the law stands as it was originally passed and the duty of reporting lies with the Clerks.

Very truly yours,

L. VERNON BRIDGES, M.D.

P. S.—I enclose a copy of the law on criminals. I am sorry I have not a printed copy of the law establishing a Division of Mental Hygiene, but I will obtain one if you wish it.

[CHAP. 415.]

AN ACT PROVIDING FOR AN INVESTIGATION BY THE DEPARTMENT OF MENTAL DISEASES AS TO THE MENTAL CONDITION OF CERTAIN PERSONS HELD FOR TRIAL.

Be it enacted, etc., as follows:

Chapter one hundred and twenty-three of the General Laws is hereby amended by inserting after section one hundred the following new section:—*Section 100.1.* Whenever a person is indicted by a grand jury for a capital offense or whenever a person, who is known to have been indicted for any other offense more than once or to have been previously convicted of a felony, is indicted by a grand jury or bound over for trial in the superior court, the clerk of the court in which the indictment is returned, or the clerk of the district court or the trial justice, as the case may be, shall give notice to the department of mental diseases, and the department shall cause such person to be examined with a view to determine his mental condition and the existence of any mental disease or defect which would affect his criminal responsibility. The department shall file a report of its investigation with the clerk of the court in which the trial is to be held, and the report shall be accessible to the court, the district attorney and to the attorney for the accused, and shall be admissible as evidence of the mental condition of the accused. [Approved May 20, 1921.]

PROMOTIONS AND APPOINTMENTS

The Board of Scientific Directors of the Rockefeller Institute for Medical Research announces the following promotions and appointments:

Dr. Wade H. Brown, hitherto an Associate Member in Pathology and Bacteriology, has been made a member.

Dr. Homer F. Swift, hitherto an Associate Member in the Department of the Hospital, has been made a Member.

Dr. Carl A. L. Binger, hitherto an Assistant in the Department of the Hospital, has been made an Associate.

Dr. Albert H. Ebeling, hitherto an Assistant in Experimental Surgery, has been made an Associate.

Dr. Laura Florence, hitherto an Assistant in the Department of Animal Pathology, has been made an Associate.

Dr. Albert B. Hastings, hitherto an Assistant in the Department of the Hospital, has been made an Associate.

Dr. Philip D. McMaster, hitherto an Assistant in Pathology and Bacteriology, has been made an Associate.

Dr. Louis A. Mikeska, hitherto an Assistant in Chemistry, has been made an Associate.

Dr. Ida P. Rolf, hitherto an Assistant in Chemistry, has been made an Associate.

Mr. Fred A. Taylor, hitherto an Assistant in Chemistry, has been made an Associate.

Dr. Hugh J. Morgan, in the Department of the Hospital, has been appointed Resident Physician at the Hospital.

Dr. David L. Hitchcock, hitherto a Fellow in General Physiology, has been made an Assistant.

Mr. James M. Neill, hitherto a fellow in the Department of the Hospital, has been made an Assistant.

Mr. Henry S. Simms, hitherto a Fellow in chemistry, has been made an Assistant.

The Following new appointments are announced: Prof. Karl Landsteiner, Member in Pathology and Bacteriology.

Dr. Christen Lundsgaard, Associate in the Department of the Hospital.

Dr. Thomas M. Rivers, Associate in the Department of the Hospital.

Miss Lillian E. Baker, Chemical Assistant in the Division of Experimental Surgery.

Dr. Edmund A. G. Branch, Assistant in the Department of the Hospital.

Dr. George R. Brow, Assistant in Medicine and Assistant Resident in the Hospital.

Dr. Harry W. Dahl, Assistant in Medicine and Assistant Resident in the Hospital.

Dr. Douglas R. Drury, Assistant in Pathology and Bacteriology.

Dr. Geoffrey C. Linder, Assistant in Medicine and Assistant Resident in the Hospital.

Dr. Henry A. Murray, Jr., Assistant in the Department of the Hospital.

Mr. Frederic M. Nicholson, Assistant in Pathology and Bacteriology.

Miss Ida W. Pritchett, Assistant in Pathology and Bacteriology.

Dr. Harold A. Salvesen, Assistant in Medicine and Assistant Resident in the Hospital.

Dr. Harold J. Stewart, Assistant in Medicine and Assistant Resident in the Hospital.

Dr. Chester M. Van Allen, Assistant in Pathology and Bacteriology.

Miss Helen A. M. Tibbotts, Fellow in the Department of Animal Pathology.

Dr. Peyton Rous, Member of Pathology and Bacteriology, has been appointed co-editor of the *Journal of Experimental Medicine*.

Dr. Harold L. Amoss, hitherto an Associate Member in Pathology and Bacteriology, has accepted a position as Associate Professor of Medicine at Johns Hopkins Medical School.

Dr. Lloyd D. Felton, hitherto an Associate in Pathology and Bacteriology, has accepted a position as Assistant Professor in Preventive Medicine and Hygiene at the Harvard Medical School.

Dr. Raymond G. Hussey, hitherto an Associate in Bio-Physics, has accepted a position as Assistant Professor in Pathology in Cornell University Medical College.

Dr. Robert L. Levy, hitherto an Associate in the Department of the Hospital, has accepted a position as Associate in Medicine at the College of Physicians and Surgeons, Columbia University, and Assistant Visiting Physician at the Presbyterian Hospital.

Dr. Edgar Stillman, hitherto an Associate in the Department of the Hospital, has accepted a position as Associate in Medicine at the College of Physicians and Surgeons, Columbia University, and Assistant Visiting Physician at the Presbyterian Hospital.

Dr. Gersony O. Brown, hitherto an Assistant in Pathology and Bacteriology, has accepted a position as Assistant in the Thorndyke Laboratory, Boston, Mass., and Assistant Resident Physician at the Boston City Hospital.

Subjects and weights.—Competitors will not be required to report for examination at any place, but will be rated on the following subjects, which will have the relative weights indicated:

Subjects.	Weights.
1. Specimen slides (to be filed with application).....	50
2. Education, training, and experience.....	50
Total	100

Applications.—Applicants should at once apply for Form B312, stating the title of the examination desired, to the Civil Service Commission, Washington, D. C.; the Secretary of the United States Civil Service Board, Customhouse, Boston, Mass.; New York, N. Y.; New Orleans, La.; Honolulu, Hawaii; Post Office, Philadelphia, Pa.; Atlanta, Ga.; Cincinnati, Ohio; Chicago, Ill.; St. Paul, Minn.; Seattle, Wash.; San Francisco, Calif.; Denver, Colo.; Old Customhouse, St. Louis, Mo.; Administration Building, Balboa Heights, Canal Zone; or to the Chairman of the Porto Rican Civil Service Commission, San Juan, P. R.

Applications should be properly executed, excluding the medical certificate, and must be filed with the Civil Service Commission, Washington, D. C., prior to the hour of closing business on August 15, 1922.

GRADUATE NURSE. GRADUATE NURSE (FOLLOW-UP).

Applications will be rated as received until December 30, 1922.

The United States Civil Service Commission announces an open competitive examination for graduate nurse, and graduate nurse (follow-up), for filling vacancies in the United States Veterans Bureau and in the Indian and Public Health Services.

Salary.—*Indian Service*.—The usual entrance salary for this position in the Indian Service is \$840 a year, with laundry of uniform, furnished quarters, heat, and light. Meals are furnished at cost. Appointees whose services are satisfactory may also be allowed the increase granted by Congress of \$20 a month.

Veterans Bureau and Public Health Service.—In the nursing services of the Veterans Bureau and U. S. Public Health Service the rates of pay are as follows, appointments being made to the lower grades and according to assignment and experience disclosed by the examination; the higher grades are usually filled by promotion:

U. S. Public Health			
Hospital Service.		Veterans Bureau. Service.	
Chief nurse	\$1,581 a year	\$1,344 a year	
Assistant chief nurse.....	1,200 a year	900 a year	
Head nurse	1,020 a year	750 a year	
Nurse	900 a year	720 a year	

In addition, quarters, subsistence, and laundry are furnished; and, in the Public Health Service only (not in the Veterans Bureau) the congressional bonus of \$20 a month is allowed.

Nurses assigned to patients having tuberculosis or neuro-psychiatric conditions are allowed increased compensation at the rate of \$60 a year.

Follow-up work in district or subdistrict managers' offices, U. S. Veterans Bureau, to be selected from those passing as graduate nurses (Public Health):

Chief nurse, \$2,000 a year.
Head nurse, \$1,500 a year.
Staff nurse, \$1,170 a year.

Nurses having special experience in psychiatry, \$1,800 to \$2,400 a year. These employees do not receive quarters, subsistence, laundry, or the congressional bonus.

Citizenship and sex. All citizens of the United States who meet the requirements, both men and

UNITED STATES CIVIL SERVICE EXAMINATION—MICROSCOPIST.

RECEIPT OF APPLICATIONS TO CLOSE AT 8:15, 1922.

The United States Civil Service Commission announces an open competitive examination for microscopist. A vacancy in the Public Health Service, for duty at Memphis, Tenn., at \$1,500 a year, and vacancies in positions requiring similar qualifications, at this or higher or lower salaries, will be filled from this examination, unless it is found in the interest of the service to fill any vacancy by reinstatement, transfer, or promotion.

Duties.—The duties of the appointee will consist of the preparation and identification of histological material, microscopic slides, and the general duties of an expert technician in a pathological laboratory.

women, may enter this examination; appointing officers, however, have the legal right to specify the sex desired in requesting certification of eligibles. For the Indian Service women only are desired; for the Veterans Bureau and Public Health Service both men and women are desired.

BOOKS RECEIVED FOR REVIEW.

The JOURNAL acknowledges the receipt of the following books for review:

Los Maladies Parasitaires des Plantes—Infestation-Infection. Par M. Nicolle et J. Magron. Published by Masson & Co, Paris. 199 pages. Price 8 francs.

Applied Chemistry—By Fredus N. Peters. Published by C. V. Mosby Co., St. Louis, Mo. 461 pages. Price \$3.50.

Symptoms of Visceral Disease. 2nd Edition. Francis M. Pottenger. Published by C. V. Mosby Co., St. Louis. 357 pages. Price \$5.50.

Studies from The Rockefeller Institute for Medical Research. Reprints—Vol. xli. Privately printed. 642 pages. Price \$2.

Blood Transfusion. By Geoffrey Keynes. Oxford Medical Publications. 166 pages. Price \$3.

Treatment of Injuries of the Peripheral Spinal Nerves. By Sir Harold J. Stiles and M. F. Forrester-Brown. Oxford Medical Publications. 180 pages. Price \$4.30.

Reports of the St. Andrews Institute for Clinical Research. Vol. 1. Oxford Medical Publications. 208 pages. Price \$3.

Psychoanalysis and the Drama. By Smith Ely Jelliffe and Louise Brink. Published by Nervous and Mental Disease Publishing Co., Washington and New York. 162 pages. Price \$3.

Tuberculosis and the Community. By John B. Hawes. 2nd. Published by Lea & Febiger, Phila. and New York. 168 pages. Price \$1.75.

Clinical Laboratory Technique for Nurses. Revised Edition. Anna L. Gibson. Published by Whitcomb and Barrows, Boston. 214 pages. Price \$2.

X-Ray Dosage in Treatment and Radiography. By William Daniel Witherbee and John Kemmer. Published by the Macmillan Co., New York. 87 pages. Price \$1.75.

Food, Health and Growth. By L. Emmett Holt. Published by the Macmillan Co., New York. 273 pages. Price \$1.50.

MASSACHUSETTS DEPARTMENT OF PUBLIC HEALTH.

CASES REPORTED WEEK ENDING JULY 15, 1922.

Disease	No. of cases	Disease	No. of cases
Anterior poliomyelitis	5	Scarlet fever	45
Chicken-pox	24	Septic sore throat	1
Diphtheria	103	Syphilis	42
Dog-bite requiring anti-rabic treatment	17	Suppurative conjunctivitis	7
German measles	2	Trachoma	1
Gonorrhea	91	Tuberculosis,	
Malaria	2	pulmonary	128
Measles	349	Tuberculosis,	
Mumps	54	other forms	21
Ophthalmia, neonatorum	9	Typhoid	13
Pneumonia, lobar	24	Whooping cough	112

PUBLIC HEALTH LECTURERS FOR THE YEAR 1922.

The Committee on Public Health of the Massachusetts Medical Society has been able during the past three years to arrange with well known specialists in various medical fields to give talks at meetings of the District Medical Societies on subjects of interest and importance to all practitioners. It is a pleasure to announce that a similar arrangement has been made this year and that the gentlemen named below are willing, without expense to the District Society, to give occasional talks of thirty to forty minutes on subjects relating to the promotion of public health, extending opportunity for questions and discussion. It is suggested that medical societies consider meeting at neighboring public institutions, since such meetings have been most successful in the past, particularly at the tuberculosis sanatoria and state hospitals for the insane.

José Penteadó Bill, M.D., Doctor of Public Health, Specialty: Preventive Medicine.

Frank C. Dunbar, M.D., Bacteriologist, Instructor in Bacteriology and Pathology, Tufts College Medical School.

Walter E. Fernald, M.D., Superintendent, Massachusetts School for the Feeble-minded.

Timothy Leary, M.D., Professor of Pathology, Tufts College Medical School; Medical Examiner, Suffolk County.

Edwin H. Place, M.D., Physician-in-Chief, South Department, Boston City Hospital. Specialty: Contagious Diseases.

C. Morton Smith, M.D., Chief of Department of Syphilis, Massachusetts General Hospital.

George Gilbert Smith, M.D., Assistant in Department of Genito-Urinary Diseases, Massachusetts General Hospital. Specialty: Genito-Urinary Diseases.

Lesley H. Spooner, M.D., on Staff of Out-Patient Department, Massachusetts General Hospital, Specialty: Specific Diagnosis and Treatment of Pneumonia.

William C. Woodward, M.D., Ex-Health Commissioner, City of Boston.

George H. Wright, D.M.D., Lecturer on Dental Hygiene, Harvard Dental School. Specialty: Dental Surgery.

Thomas F. Kenney, M.D., Director of School Hygiene, City of Worcester. Specialty: Full time School Health Officer.

Secretaries of District Medical Societies writing to ask for these lecturers will kindly designate the topic, the place and the hour of meeting as well as the name of the desired speaker, thus eliminating unnecessary correspondence. Please address communications to the Secretary of the Committee, Annie Lee Hamilton, M.D., 164 Longwood Ave., Boston 17.

[Note: The Committee on Public Health feels that this notice may have escaped attention, for few applications have been received. Each lecturer is an authority and would present his subject in an interesting and instructive manner.]

MEETING OF APRIL 26, 1922.

SUBJECT OF THE EVENING: ENDOCRINE THERAPY.

A CRITICAL CONSIDERATION OF ENDOCRINE THERAPY.

By W. B. Cannon, M.D., Boston.

NOEL PATON entitled his little book on the endocrine glands "The Regulators of Metabolism." But these glands have other functions than that; they regulate growth, they determine the development of intelligence; they fix the appearance of the secondary sexual characteristics and the regular sequences in reproduction, and they control the nature and rate of the chemical changes which take place in the body. There is no question of the importance of these glands and of their capacity to cause very profound disturbances in all the above-mentioned processes. It is only fair to ourselves, however, and to a satisfactory development of the knowledge of the functions of these glands, that we recognize the present limitations of our ability to control these "controllers" and see clearly the dangers of using careless methods and of making hasty inferences.

In justification of these strictures it may be said, first of all, that we lack reliable clinical tests of the defective functioning of the endocrine glands. We have a good clinical test for the over-functioning of the thyroid gland,—the increased metabolism. This increase in cases of "hyperthyroidism" is not paralleled by any other pathological state. But we have no similarly trustworthy way of judging the operations of other glands. It is very common to attribute low blood pressure to hypoadrenalism, and to attribute high blood pressure to hyperadrenalism. There is no evidence whatever that the blood pressure is maintained by the secretion of adrenalin. In many different kinds of animals a small amount of adrenalin causes a fall of blood pressure rather than a rise. Furthermore, it has been shown that an amount of adrenalin which is necessary to induce a rise of blood pressure will stop the whole process of digestion. Dr. Aub has shown that after removal of the adrenal glands an animal may have no fall of blood pressure for two or three days. Stuart and Rogoff have removed one adrenal gland and severed the nerves to the other so that there was no secretion, and kept the animals thus operated upon in normal condition, for months. In the face of such evidence, to attribute a low blood pressure to absence of adrenal secretion is wholly unjustified. Similar remarks could be made about such conditions as adiposity or short stature in relation to these glands. These

conditions may be due to a variety of widely different causes. Furthermore, it is necessary to discriminate between what may be an immediate sequence of disturbance in the functioning of an endocrine gland and the results of secondary changes in other glands before we can decide what is the rational course to pursue.

We are largely ignorant of the ways in which agents are effective when they are administered. In literature which is widely distributed at the present time and in medical writings the giving of adrenalin by mouth is commonly advocated. There is clear evidence that relative to the physiological output enormous amounts of adrenalin can be given by mouth with no effect whatever. Either the substance is destroyed in the alimentary tract or it is absorbed so slowly that it has no influence. Recently it has been found that after an animal is deprived of the pancreas, the high blood sugar can be brought down sharply to normal by intravenous injections of an extract of the pancreas, but that the extract has no effect if given by mouth.

There is a danger in the misuse of endocrine products which is shared by all other therapeutic agents. For example, the misuse of adrenalin and pituitary extract in the treatment of shock. In a state of shock there is evidence that the individual is suffering from diminished blood volume, which fails to fill the circulatory system even though the blood vessels are greatly contracted. After the giving of pituitrin or adrenalin arterial pressure may be increased, but the circulation has not been improved in the essentially important capillary area. The action of these drugs is to constrict the arterioles. This dams up the blood in the arteries and, if anything, checks the circulation in the capillaries.

Certain fallacies ought to be borne in mind in dealing with these substances. They are frequently given in the belief that there is a deficiency of one gland or another. For example, because pituitrin will cause contraction of the uterus in labor it has been supposed that it is the natural function of the pituitary to stimulate the uterus during labor. That is a fallacy dependent upon the failure to recognize that pituitrin is a drug with a pharmacodynamic action. There is no evidence that pituitrin acts in the body as it does when given as a drug. We are not at all justified in drawing inferences from the therapeutic effect of a drug made from these glands as to their physiological rôle in the body.

A second fallacy is dependent on the use of polyglandular therapy. There is a tendency to believe that all the substances included in the mixture are effective. All the agents may get credit for a single one contained in the mixture. An analysis of a number of cases in which such a compounded preparation had been used with extraordinary effect showed that they could all be reasonably regarded as cases of hypothyroidism and that the thyroid substance in the mix-

ture had wrought its usual changes in such conditions.

Another fallacy lies in the claim that there is a condition of the body known as "hormone hunger," that is, that when a gland is absent or deficient and a mixture of gland substances is given the body will take from the mixture what it needs and will neglect the rest. That is pure theory. It is not commonly true of therapeutic agencies. It is not true of thyroid substances, for example, for thyroid can be given until it produces a very distressing condition. The body does not neglect it, but suffers from it.

I believe as we make progress in our knowledge of endocrine therapy we shall get greater and greater control of the bodily processes. Most of the original progress in endocrinology was made by clinical observers. That fact deserves emphasis. The clinics receive varieties of disturbances that are very difficult to reproduce in the laboratory. What is needed for progress is not this confusing, misleading use of mixtures of all sorts, but a careful use of single agents, rationally chosen, so that when results are obtained they may be attributed to the agent used. My plea is for a critical attitude in the presence of the present wave of enthusiasm for endocrine interpretations of medical disorders and for endocrine treatment of all sorts of complaints. Throughout the history of medicine advance has been made by critical study and not by simple faith. Furthermore, silliness on the part of the credulous has a tendency to repel the more sober-minded, so that persons who are most needed for the development of new knowledge in endocrinology are not encouraged to undertake the task.

THE USE AND ABUSE OF THYROID.*

BY J. H. MEANS, M.D., BOSTON.

Although little enough is known of the function of any of the endocrine glands, I am inclined to believe perhaps that little is greater in the case of the thyroid than in that of any of the others. There are definite syndromes which we associate clinically with over or underactivity of the thyroid which can be closely paralleled artificially through thyroid feeding in the one case or thyroidectomy in the other. Furthermore, in the case of the thyroid a substance has been isolated in pure chemical form, which in many respects behaves as though it were the active principle, or perhaps better one of the active principles of the gland. This substance has been called thyroxin by its discoverer, Kendall.¹

The functions of all the endocrine glands are unquestionably closely interrelated, but the manner of these interrelationships is very imperfectly understood. Many of the hypotheses

*Such original work of the author and his associates as is referred to in this paper has been aided in part by a gift from Dr. William Norton Bullard.

that have been elaborated concerning them rest upon a very scanty basis of fact. In general, it may probably be said with truth that all of the endocrine glands are in some way concerned in the two great processes of metabolism and growth, both of these terms being taken in their broadest sense.

The most conspicuous function of the thyroid, in so far as we know its functions, is its regulation of the rate of oxidation within the body, or of the rate of energy transformation in living cells. Other glands than the thyroid are concerned in this regulation, notably the adrenal, and to a less extent the pituitary, but less strikingly so than is the thyroid. Furthermore, the thyroid probably has other functions than the regulation of the thermogenesis, as shown, for example, by the work of Hunt,² who found that thyroid feeding decreased the susceptibility of animals to certain poisons.

In spite of these other functions, however, it is chiefly in its rôle of governor to the human engine, or, if you will, damper to the human furnace,* that the thyroid presents itself to the attention of the clinician. Overactivity of the thyroid is characteristically manifested by an increased rate of combustion within the body; underfunction by a decrease. A knowledge of this fundamental principle of thyroid activity enables us to understand the alterations of thyroid function seen clinically. The signs and symptoms of toxic goitre, for example, the flushed skin, the increased sweating, and the sensation of warmth, are the direct result of an increased heat elimination, while the increased circulation rate, the loss of body weight, and the compensatory appetite increase may be regarded as the direct result of increased heat production. Similarly, the cardinal manifestations of myxedema,—the lack of sweating, the chilliness, the sluggish circulation and the gain in weight,—may be explained on the basis of decreased heat production and elimination.

The purpose of the present paper is to discuss briefly the indications and contraindications for thyroid therapy. We cannot use a drug intelligently unless we know its pharmacologic action, nor can we intelligently treat disease unless we have some understanding of the functional and structural pathology involved. In the case of thyroid therapy we are using as a drug a normal constituent of the body. We know something of the function of the gland as it exists in the body and of its action when given as a drug. We should, therefore, be in a good position to see when thyroid should be used therapeutically as well as when it should not.

Let us consider for a moment the effect of thyroid when given to a normal man. In Figure 1 is shown an experiment performed by my associates, Dr. W. G. Lennox and Miss H. W. Burgess. The ingestion of dried thyroid gland

FIG. 1. Effect of thyroid on a normal man. The heavy black line denotes basal metabolism; the interrupted line, pulse.

for six days caused a gradual rise in the rate of metabolism and pulse and produced certain definite symptoms, such as palpitation. The chief point which I should like to emphasize is the relatively slow action of thyroid. The maximum rise in pulse and metabolism did not occur until the seventh day and the effect took some nine days more to wear off. This effect of thyroid on metabolism is similar in character to that of adrenalin. I hope that Dr. Aub will later tell us about the adrenal effect. The adrenal seems to be a rapid, the thyroid a slow action.

In contrast with the thyroid feeding curve are those obtained by Marine and Lenhart,³ after complete thyroidectomy in rabbits. As we should expect, they show essentially the diametric opposite effect. A drop in metabolism of a similar order of magnitude has been observed by Aub and myself in a woman in whom Dr. Brewster did an extensive thyroidectomy for thyroiditis.⁴

These facts emphasize what is news to no one, that thyroid administration is indicated in hypothyroidism. The rapid relief of the symptoms of myxedema by the giving of thyroid gland is one of the great advances of modern medicine. But just because we have this highly potent agent at hand to cure certain pathologic states, just so much the more should we be on our mettle to diagnose them. Frank myxedema and cretinism should offer no difficulties, and yet I think many of us have seen typical cases of the former which had been regarded as nephritis for years. It is the atypical case of

*Neither of these analogies is strictly correct, but they have value suggestive.

FIG. 2. Effect of thyroid in a case of myxedema. The heavy black line, in this and in Figure 3, denotes basal metabolism, the interrupted line pulse, and the dotted line body weight. The observations of Oct. 2 and 5, 1914, were before thyroid, the subsequent ones during the administration of thyroid. It will be seen that for the most part the dosage was so regulated that the metabolism stayed essentially within normal limits.

FIG. 3. Effect of thyroid in another case of myxedema. The observations of Nov. 13 and 14, 1914, were before thyroid, that of Nov. 23 after. The patient left the hospital in the middle of December, 1914, and was not seen again until July 14, 1920. She had taken thyroid for six months after leaving the hospital, and then very irregularly for a few months more. She had had none at all for a year previous to July 14, 1920. Her symptoms and signs of myxedema were more pronounced than ever. The second course of thyroid promptly brought her to a normal state and she has remained so ever since. One observation has been recorded since the above drawing was made. On Jan. 5, 1922, the metabolism was 5 per cent, the pulse 89, and the weight 73 kg. The dose of thyroid has remained the same.

hypothyroidism that will tax our diagnostic acumen. At present the clinical use of calorimetry offers a valuable aid in the recognition of these borderline cases.^{5,6} In the presence of symptoms suggestive though not typical of myxedema, the finding of a subnormal metabolic rate justifies the administration of thyroid gland, and in both the typical and atypical cases of hypothyroidism the further observation of the basal metabolism will provide a guide to the

proper dose of the drug for the given individual. As is shown by the charts of some of our myxedema patients (Figures 3 and 4), the aim should be to give sufficient thyroid to raise the metabolism to a normal level and keep it there, but not to give enough to produce hyperthyroidism.

In certain types of goitre there may be an indication for the administration of thyroid or thyroxin. Certainly not in exophthalmic goitre nor in adenoma with hyperthyroidism, for in these the body is already suffering from an excess of thyroid secretion, but in certain diffuse colloid goitres, as pointed out by Plummer,⁷ there may be an actual deficiency of thyroid secretion available for the tissues. The goitre under such circumstances is the result, not the cause, of the hypothyroidism. In cases of this type, he has found, the administration of thyroxin will diminish the size of the gland and fails to produce the symptoms which thyroxin would in a normal person. These patients have basal metabolic rates of 8 per cent. to 15 per cent. below the average normal.

The next problem which presents itself is whether thyroid therapy is ever indicated in conditions which are not clearly those of hypothyroidism. In his textbook of pharmacology and therapeutics Dr. H. C. Wood, Jr.,⁸ says: "The diseases in which the thyroid body has been given include nearly all the chronic and many of the acute troubles known to humanity; in some of them it has seemed of benefit. In most it has proved useless." We cannot even enumerate them here. The list includes such varied conditions as dysmenorrhoea, psoriasis, heart block and the non-union of fractures. In none of them has the result of thyroid therapy been so obviously good as to make the adoption of that form of therapy general.

By far the most important problem from the point of view of the practitioner is whether it is legitimate to use thyroid in the treatment of obesity. I have expressed the view in the past that it is not legitimate. My reasons were that, having found that in simple obesity there was no alteration of basal metabolism, I believed that no element of hypothyroidism existed, and that, therefore, the effect of giving thyroid would be to produce hyperthyroidism. It might be objected to this argument that thyroid does reduce weight and that a mild grade of hyperthyroidism if not long continued does no great harm. Perhaps this may be true in certain instances, but I have repeatedly seen patients, particularly those who are no longer young, in whom the use of thyroid has produced very definite circulatory symptoms, palpitation, precordial pain and sometimes even attacks suggesting angina pectoris, symptoms which to my mind cannot be regarded lightly. Furthermore, it is a matter of common experience that the weight-reducing power of thyroid in obesity is uncertain and oftentimes of short duration. A part is due

merely to loss of water, for one effect of thyroid is the production of diureses.

I still feel that in the routine treatment of obesity thyroid is undesirable. I do not wish to give the impression that I am opposed to all empiric therapy. Many of the advances in medicine have been made through empiricism, but if one uses thyroid empirically he should do so with the greatest care. It is a very different matter to give thyroid to a patient under daily observation in a hospital, where pulse, weight, metabolism and symptomatology can be constantly observed, to ordering it for a patient not to be seen again for several weeks. The former may be legitimate where the latter is not.

For example, in the treatment of obesity I am permitted through the kindness of Dr. Edward H. Mason to refer to two cases treated by him in the Royal Victoria Hospital, Montreal. These patients, both women, were treated by a combination of extremely low diet, under 500 calories per day, and thyroid, the dose varying between three and fourteen grains per day. This programme was entirely legitimate under the circumstances, both patients being under close observation in a metabolism ward throughout their treatment, and the results obtained justified the methods used. The treatment lasted some fifteen weeks, during which time one patient lost 29, the other 36 kg. The basal metabolism, observed frequently, in one patient never went above +8.6 per cent., but in the other once rose to +21 per cent. The latter was, therefore, for a brief interval, rendered thyrotoxic, but it apparently did no harm.

The fact that Dr. Mason coupled his thyroid therapy with a diet just short of starvation is to my mind one of the most important features of his work. Benedict⁹ has shown that the effect of prolonged undernutrition is to reduce the rate of metabolism, that of giving thyroid is to raise it. It may well be that patients on very low diets tolerate thyroid better than those on more liberal ones. It is not at all impossible that the lowered metabolism in starvation is a compensatory mechanism on the part of nature to reduce tissue loss to a minimum. If one did not wish to save tissue, but to burn it, one might accomplish it by starving and giving thyroid at the same time. One wonders, however, what would have happened in Dr. Mason's cases with the dietary restriction alone. In 1915 I reported observations on an obese woman who was reduced 10 kg. in 36 days by a system of intermittent fasting.¹⁰ She lost weight, therefore, at about the same rate but without the use of thyroid.

Another important phase of thyroid therapy is the use of this drug by the laity. The profession, of course, is deluged with propaganda from unprincipled drug promoters telling of the nearly universal helpfulness of organotherapy. Let us hope that the majority of physicians will be duly skeptical. It would seem

though that enough are credulous to make the advertising profitable. It is, however, the direct self-dosing by the laity that is most fraught with danger. In certain instances the public is urged to take thyroid as a general prophylactic agent and cure-all. The use of thyroid without a physician's advice, in order to reduce weight, is quite common.

For example, a graduate nurse has kindly collected certain data for me regarding the use of thyroid by the pupils in a girls' boarding school in Massachusetts. The local druggist sold it over the counter to anyone wishing it. Such self-dosing was quite contrary to school rules, but was difficult to stop. The craze among the girls was to be thin and to have lissome figures; the thyroid, it was hoped, would secure the fulfillment of this ambition. The histories of two girls were obtained in detail. Miss A., 17 years old, took ten grains a day for three weeks, when she began to feel weak, to have increased sweating, nausea and more or less headache. She took the thyroid because a kind relative told her it would make her thin. It apparently did so temporarily, for she lost twenty pounds, but it made her sick also. Miss B. took thyroid upon the advice of Miss A. She took ten grains a day for two weeks, then about eight grains a day for another week, after that took it irregularly, sometimes five grains, sometimes ten or twelve, extending over a period of five or six weeks. She lost seventeen pounds and also developed nausea, vomiting, headache, anorexia, loss of appetite, extreme nervousness and insomnia. Her pulse rose to 110. After the drug had been stopped the nervous condition persisted for several months, gradually clearing up.

CONCLUSIONS.

In conclusion it seems fair to say:

1.—That in thyroid we have a highly active drug. The conspicuous feature of its action is the increasing of the rate of combustion within the body and the production of the symptoms associated therewith.

2.—That certain clinical conditions exist in which a low metabolic rate is undoubtedly due to underactivity of the thyroid. That in such the administration of thyroid relieves all symptoms. That certain types of non-toxic goitre may be included in this group.

3.—That in conditions other than hypothyroidism no conclusive indications for the use of thyroid have yet been found.

4.—In normal persons the ingestion of thyroid produces unpleasant if not harmful symptoms. In these persons it does the same. In simple obesity there probably is no element of hypothyroidism. The use of thyroid in the routine care of obesity would therefore be unwarranted. An exception may be made when thyroid therapy is coupled with partial starvation.

5.—Whenever thyroid is used in conditions other than hypothyroidism—in obesity, for example, or empirically in other conditions—it should be used with the greatest caution. The physician should have a full understanding of its action and of the harm it may do, and have his patient under careful observation, so that the drug may be stopped at once if ill effects arise.

6.—Self-dosing with thyroid by the laity is highly undesirable. The profession should do its utmost to discourage this practice.

ADRENAL THERAPY.

By C. H. LAWRENCE, M.D., BOSTON.

The scope of this paper allows only brief mention of certain uses of adrenal gland extract. More common uses to which adrenalin is put depend, not upon its general effect on the physiology, but upon its local action on certain structures. Its use in surgery and laryngology is well understood and need not be discussed here. Its effect in relieving bronchial spasm in asthma and the skin manifestations of protein sensitization has been clearly demonstrated.

When, however, attention is turned to the effect of adrenal secretion upon the body in general, and its usefulness as a therapeutic agent, the greatest obscurity and conflict of opinion is encountered. Clinical medical literature is crowded with articles claiming that a variety of conditions, from epilepsy to post-infectious debility, are due to malfunction of the adrenals, and can be cured by the administration of adrenalin or adrenal extract plus one or more other glandular derivatives. Laboratory workers reply that they are unable to substantiate these claims by means of animal experimentation, and the clinician replies that he is treating sick human beings, not experimental animals. Add to this situation the propaganda of various manufacturers, whose only purpose is to exploit glandular therapy in general, and the situation becomes nearly hopeless.

The only hope at all lies in the fact that slowly, through research, a little more is becoming known and a little less suspected concerning

the adrenal and other endocrine glands, and that here and there clinicians are doing scientific work upon the subject.

There are, however, certain important points on which clinician and laboratory worker differ. These I wish briefly to call to your attention. The first is the effect of adrenalin on blood pressure. It has been shown by animal experimentation that injection of adrenalin causes a rise in blood pressure. From this fact it has been argued that the secretion of the adrenals was the important factor in maintaining blood pressure in man, and as a corollary, that injections of adrenalin would be successful in combating the hypotension of shock.

In spite of the fact that the rise in pressure following administration of adrenalin is temporary, that it may be followed by a fall to a level lower than that which previously obtained, and that Stewart and Rogoff¹ have shown that the adrenalin output in shock is not essentially changed from normal, adrenalin was and still is used enthusiastically in many conditions in which hypotension is one of the abnormal findings. At present its use in such conditions is diminishing, as experience slowly teaches that the effect obtained is too transitory to materially benefit the patient.

Another point on which laboratory worker and clinician differ is the effect of giving extract of the whole adrenal gland by mouth. This form of treatment has been condemned as useless by the laboratory, since no typical adrenalin effect could be demonstrated on animals following the oral administration of that substance. Some clinicians have felt sure that cases of definite hyposecretion of the adrenals, if not due to tuberculosis of the glands, were benefited by oral administration of whole adrenal substance. Among others, Osborne² has recently reported such a case, and my own experience, though limited, agrees with his. The explanation lies, I believe, in Rogers'³ recent work. From his experiments with extracts of whole adrenal gland given by mouth to animals he concludes that "certain derivatives of the entire adrenal gland produce physiological reactions which differ materially from those of commercial adrenalin." Stewart⁴ says: "The experimental evidence has tended more and more to show that the cortex is the part of the adrenal indispensable for life."

It seems probable, therefore, that adrenal substance administered by mouth is of value in certain types of adrenal insufficiency. It remains to be determined exactly how it produces its beneficial effects and in what conditions it is useful. Its exhibition in every case showing low blood pressure is no more logical or successful than the use of the nitrites in every case of hypertension. The low pressure is in most instances evidence of general malnutrition or tox-

aemia in which the adrenals may share, but which they do not cause.

The great need at present is more careful study of cases of possible adrenal disease. The presence of hypotension and Sergeant's white line⁵ do not justify the use of adrenal therapy.

A careful inquiry into the history in cases of hypoadrenalism will usually bring to light a previous severe infection or abnormal nervous strain. Nervous irritability, insomnia, loss of appetite, constipation or diarrhoea, palpitation, dyspnoea, often attacks of abdominal pain, and, most important of all, lack of muscle strength and easy fatigability—some or all of these symptoms appear in the history of any patient whose adrenal function is insufficient. Physical examination will usually disclose pallor, actual muscular weakness and limited response to physical effort. Microscopic examination of the blood as a rule shows a secondary anaemia of moderate degree, with often a relative increase of the lymphocytes. Chemical examination of the blood, in my experience, shows an abnormally low sugar content. This has been previously reported by Falta,⁶ Eppinger,⁶ Bernstein,⁷ and others, and is, I believe, of considerable diagnostic value. This estimation is available to any physician and should be made in all suspected cases. I also believe, though my experience with it is too limited to be of much value, that cholesterol estimations may prove important.

When a patient's history and physical examination present a picture similar to the one I have sketched, and when the laboratory findings fit into that picture, then, and only then, is adrenal therapy justified in the present state of our ignorance. We may eventually have an easier way of making the diagnosis, but it can come only as the result of painstaking study of patients, checked by research. There must be less use of glandular extracts in obscure cases simply because the picture is obscure and the action of the endocrines is likewise obscure. If it is ever to be anything else, there must be careful observation of cases in their early and curable stage. This cannot be done in hospitals, since patients do not often come to hospitals until the disease has passed that stage. But there can be close co-operation between practitioner and laboratory, which would make the results of research more available for the test of clinical use, and would lead the practicing physician to pay more heed to proven facts and less to inspired theories.

PARATHYROID DEFICIENCY AND ITS TREATMENT.

BY FRANK H. LAHEY, M.D., BOSTON.

THE parathyroids were first described by Sandström, a Swedish anatomist, in 1880.

They were rediscovered by Gley in 1891, and his conception of their function maintained itself for approximately the succeeding ten years, namely, that it was the function of the parathyroids, by differentiating into thyroid tissue, to take up the duties of the thyroid when that gland was removed. This is now known to be untrue.

Moussu demonstrated in 1897 that complete removal of the parathyroids produced death in convulsions, now known as tetany.

The parathyroid glands vary from four to one in number. Of 64 cases studied by Laignel-Lavastine and Duham,¹ 11 had 4 parathyroids, 18 had 3 parathyroids, 15 had 2 parathyroids, 17 had 1 parathyroid, 3 had no demonstrable parathyroids. It is possible in these last three cases, and also in some of the other groups, that parathyroids were present which could not be demonstrated.

When all are present, two are located at the top of the gland, on the posterior surface, in close relation to the terminal branches of the inferior thyroid arteries, and two are located at the inferior pole of the gland, on the posterior surface, where the branches of the inferior thyroid artery and the recurrent laryngeal nerve are in close relation.

We have demonstrated parathyroid bodies a great many times in thyroid operations and have seen them present in unusual locations. The most constantly located gland has been the one at the entrance of the inferior thyroid artery, on the posterior surface close to the trachea. We have seen glands, corresponding in every way to parathyroid glands, well out toward the outer border of the posterior surface of the thyroid, and well down to the lowest portion of the gland where the inferior thyroid veins and thyroidea ima artery enter the gland; likewise, a presumably parathyroid gland lying directly on the anterior inferior surface of the thyroid near its outer border; and, also, superior parathyroids entirely free from the thyroid gland lying within the bundle of the superior thyroid vessels just before their connection with the superior thyroid pole. Therefore it is obvious that the location and relationship of the parathyroids are by no means constant.

One of the greatest difficulties with the entire parathyroid problem is that these glands are not of sufficient size or distinctiveness to permit one to be certain of their true identity without removing and submitting them to histological examination, and it is doubtless this

fact which has resulted in such a number of contradictory results in the production of tetany in animals, and possibly in the therapeutic effects of parathyroid feeding.

The following characteristics have been noted by us in parathyroids seen in the course of several hundred thyroid operations. They are elliptical, clean-cut, brown bodies varying in size from slightly less than the head of a match up to slightly less than the smallest pea bean. They are soft, their surface is smooth and shiny, often showing the striations of fine blood-vessels beneath their covering; they are movable, elevated, and to be distinguished from lobules of thyroid tissue by the fact that on careful examination they will be found to be entirely separate from the thyroid and bound to it by delicate connective tissue in which are the nourishing vessels. Accessory parathyroids have repeatedly been demonstrated in animals and no doubt may exist at times in man.

The parathyroid bodies have been suspected of playing a part in epilepsy, myotonia, paralysis agitans, eclampsia, the infantile spasmodic, and the tetanic attacks in adults not occurring as a sequence to thyroid operations. The relationship in this group of cases is based almost solely upon the fact that the characteristic features of those diseases are tetanic in form and tetany is known to occur with removal of the parathyroid. Further, that during the tetanic attacks, particularly in spasmodic and adult non-surgical tetany, there is found, as in surgical tetany, a lowered calcium content in the blood. Suspicion as to their relationship results also from the fact that beneficial results have been claimed especially in the two last-mentioned conditions—spasmodic and non-surgical tetany—from calcium treatment which is known to be of value in surgical tetany. As to the proven relationship of the parathyroids in these diseases, there is none. No pathology of the parathyroids has been proven nor has parathyroid feeding proven of value.

Osteomalacia and rickets are bone diseases whose origin has at times been attributed to functional disturbances in the parathyroid glands. The theory of relationship in this group of bone cases has been based upon the proven fact that the improper bone development is the result of calcium deficiency, and since it is known that there is an increased calcium output in the urine and feces, and a diminished amount of calcium in the blood and brain during the tetany which follows the removal of the parathyroids in animals, and since it is known, also, that the administration of calcium to parathyroidectomized humans or animals is beneficial and in most instances controls the tetanic attacks, it is presumed that there is a relationship between these bone dis-

cases and the parathyroids. When, however, it is realized that tetany can be relieved also by acid administration (Wilson) or by infusion of soluble strontium salts (Berkeley and Beebe) as well as by calcium salts, and when it is further realized that the above-mentioned bone diseases are not influenced by the administration of either calcium or parathyroid extract, and that no parathyroid pathology is demonstrable in these conditions, the relationship as in the previous group becomes equally less tangible.

As to the administration of parathyroid extract, in the first group of cases no benefit has been obtained from its use in epilepsy, myotonia, eclampsia, the spasmodic attacks of childhood, or the non-surgical attacks of tetany. Claims have been presented as to its therapeutic value in paralysis agitans, and cases have been cited in which improvement in symptoms in this disease has been accomplished by means of transplantation of parathyroid glands. Regarding the administration of beef parathyroid in this disease, the method has now been used for several years without producing striking and convincing results. Regarding transplantations of parathyroid in paralysis agitans, a very limited number of such transplantations have been favorably reported from foreign clinics, but inasmuch as unsuccessful transplantation of parathyroids in tetanized animals and humans has been almost the universal rule, one must accept these one or two cases only with considerable reservation. Where transplantations for tetany are done close to the onset of the disease (as they usually are), one may rightly suspect that if a cure follows the transplantation, a remaining parathyroid may have resumed its function.

Tetany following surgical parathyroidectomy may therefore be said to be the one constant and tangible state which may be directly attributed to parathyroid deficiency. It may be consistently produced by the removal of the parathyroids and in a constantly characteristic form. Unfortunately from the point of view of proof, however, it apparently is not constantly cured by the administration of parathyroid extract, as is the case in thyroid feeding in myxoedema.

It appears within two to five days following operations on the thyroid gland, one case having been reported four hours post-operative. In the complete and severe form there are convulsions, spasmodic contractions with the hands in the characteristic *accoucheur's* position, rapid respiration, salivation, and death in coma.

The mild or transitory types are due quite probably to partial parathyroidectomy, the attacks occurring when additional loads are thrown upon parathyroid tissue not sufficiently abundant to meet the unusual demand.

In this recurring and less severe type it is possible to observe the signs of the disease with greater deliberation. The earliest complaints in the three transitory cases which we have seen have been stiffness and tingling in the hands and feet, followed by spasmodic contractions of the hands and feet, with the fingers in the characteristic position of the *accoucheur's* hands, the fingers flexed at the metacarpophalangeal joint, the hand flexed at the wrist and the thumb on the palm, the arms flexed at the elbow. These attacks have passed off within a few minutes and have been controlled by the administration of calcium lactate and parathyroid extract. The condition is further characterized by Troussseau's sign, contraction particularly of the fingers and thumb on pressure over the large nerves of the arm; Chvostek's sign, a spasm of the face seen on tapping over the trunk of the facial nerve; Erb's sign, an increased irritability of the peripheral nerves to weak galvanic currents. The entire picture of the disease is one of hypersensitiveness of the peripheral and also the central nervous system.

Our own experience with tetany has been limited to three cases, all transitory in character. Two received both calcium lactate and parathyroid extract with prompt relief. One has had no recurrence of the attacks since leaving the hospital, and one has had occasional attacks at rare intervals. The third case was first placed upon parathyroid extract without effect, and later controlled by the administration of calcium lactate.

Two of the cases of tetany occurred out of 342 thyroid operations during the year 1921, and one has occurred this year, 1922, out of 128 to date. None occurred in over 500 thyroid operations previous to 1921. Our explanation of the recent occurrence of tetany in our hands is that we have in recent years felt it necessary to remove more thyroid tissue to accomplish the most complete degree of cure, and have in this way perhaps more often jeopardized the viability of the parathyroids. We regret that in each of our three cases separate medication as in the last was not tried out, submitting the patient first to parathyroid extract and later, if necessary, to some form of calcium administration.

Since there seemed to be a divergence of views regarding the therapeutic value of parathyroid extract, we sent a questionnaire to a number of surgeons as to their success in treating tetany, the type of treatment used, and the results.

Two reported that they had used parathyroid extract alone, successfully controlling the tetany. Of these two, one states that dried beaver parathyroid controlled the attacks promptly, but that later the patient was given calcium in small doses which sufficed to control

the manifestations. The other reports that calcium lactate had no effect, but that parathyroid extract by mouth controlled the symptoms at once. This patient died later, however, in epileptic convulsions.

One reports definitely that his experience with parathyroid extract has been unsatisfactory.

One clinic reports that they have not used it for a year, employing calcium instead.

One reports giving as high as 15 grains of parathyroid extract a day. He does not think it was of value, but used calcium lactate with it. Signs disappeared in two weeks. In his opinion recovery was due to spontaneous return of function.

One reports parathyroid used without effect, but comments that the preparation might have been old.

One reports that in his experience ordinary parathyroid extract tablets have been entirely useless, and states that repeated use of the microscope has satisfied him that the material may be of another character and seldom is really parathyroid.

Seven report very satisfactory results with calcium in the form of calcium lactate; one of the seven states that he at times employs calcium bromide, and one that he employs calcium chloride 10 per cent. sol. 5 c.c. intravenously, taking care that it is introduced slowly, as painful indurations follow its diffusion into the tissues.

One reports that all cases are given calcium post-operatively in view of the possibility that they may show tetany (calcium chloride elix. 2 drachms T. i. d.).

Two, excluding our own experience, employed parathyroid extract combined with calcium.

From the foregoing it seems quite probable that at least the average parathyroid extract is of doubtful value, and that calcium in the form of lactate or chloride is more dependable. It is further probable that particularly during the attacks when prompt relief is sought, the administration of calcium intravenously results in more prompt effect than when given by mouth, where absorption is slow. It seems probable, also, that when given by mouth, in fairly large doses, 15 to 20 grams of the lactate, provided it does not produce nausea, should be given.

It is impossible from the data which we have at hand to estimate other than roughly the incidence of tetany in thyroid operations. We have totaled the number of cases of tetany and the number of thyroids operated where this data was given in the replies, with the following result:

In approximately 5600 operated thyroid cases, tetany appeared in 27 cases, of which number three were fatal within a short time

and 24 were apparently transitory in character. Except in our own three cases, which are progressing favorably, we have no facts as to the eventual outcome in the transitory cases.

There is much experimental evidence upon which to base calcium feeding in this condition. Wilson, Stearns, and Thurlow² demonstrated in tetanized dogs that an alkalinity of the blood develops after parathyroidectomy, and that the same lowering of the alkalinity may be accomplished with calcium as after the injection of acid.

The electric irritability which is increased in tetany when the calcium content is low (Erb's sign, increased irritability of peripheral nerves to galvanism) has been shown by Rosenstern³ to be diminished when large quantities of calcium are administered by mouth.

Peripheral Irritability.—MacCallum has shown that, if the extremity of an animal be perfused with blood from a parathyroidectomized animal or blood from which the calcium has been removed, the electric irritability is increased, and if the limb is again perfused with normal blood the hypersensitiveness in this part disappears.

MacCallum has proved that the effect of the poison is upon the nerves and not the muscles by cutting the innervation of a muscle away and not obtaining the tetanic contraction with tetany which is obtained when the innervation is complete.

In addition to the above, tetany has been brought about both in children and in adults by the administration of soda bicarbonate. It has also been produced by voluntary prolonged hyperpnoea, probably as a result of the disturbance of the acid-base equilibrium in the body, producing an increased alkalinity of the blood and urine, a diminution in the plasma bicarbonate, and a lower carbon dioxide tension.

As has previously been stated, MacCallum has demonstrated in tetanized animals an increased output of calcium in the urine and the feces and a lowered amount in the blood and brain.

CONCLUSIONS.

Tetany undoubtedly follows complete removal of all of the parathyroids.

It occurs in two forms, mild and transitory, or severe and fatal.

Parathyroid pathology has not been demonstrated in the other diseases characterized by calcium deficiencies or tetanic seizures.

Surgical tetany, therefore, is the only disease which may now be attributed to parathyroid deficiency.

Clinically and chemically it simulates other diseases which are apparently the result of disturbances in the acid-base balance.

With the appearance of its symptoms there is a definite increase in alkaline balance, a

decrease in the acid balance; and a disappearance of symptoms when this balance is restored by the administration of calcium in some form.

Calcium, therefore, by mouth in the form of calcium lactate and by vein in the form of calcium chloride or calcium lactate, is the most effective form of treatment. In transitory cases it will undoubtedly tide patients over the attacks. In the severe form it perhaps prolongs life, but death probably eventually results.

It is doubtful if the average commercial parathyroid extract is of value in surgical tetany, and it is quite certain that it is of no value elsewhere.

PITUITARY GLAND THERAPY.

By W. RICHARD OHLER, M.D., BOSTON.

In presenting a few remarks on the subject of pituitary gland therapy no attempt will be made to review the literature on the subject, nor to set up definite standards or rules of treatment. The whole subject is still none too clearly understood even by those who confess to a rather extensive use of this form of therapy. My purpose is simply to review very briefly the more generally accepted clinical signs of disturbed pituitary function and to suggest what may be expected from glandular therapy.

It is generally accepted that the clinical manifestations of pituitary disorders are produced by over-function (hyperpituitarism) or under-function (hypopituitarism) of the whole gland, and various combinations of over- or under-function of separate lobes of the gland, so-called dyspituitarism. Attempts have been made to group symptoms according to over- or under-function of separate lobes of the gland, but in the light of our present knowledge it seems best to speak only of over-function or under-function of the whole gland. In doing so use has been made of various texts and articles, but particularly of the publications of Cushing and his co-workers.

Briefly the clinical signs are as follows:

I.—Over-function (hyperpituitarism).

1.—Acromegaly and a certain type of gigantism are usually associated with hypertrophy and hyperplasia of the anterior lobe.

A.—Skeletal changes—

a.—If ossification of epiphyseal cartilages incomplete before onset of disease, changes result in a fairly normally proportioned giant.

In this connection it is well to point out that in eunuchs the skeletal changes are probably due to pituitary hyperfunction secondary to deficiency of testicular hormone. This apparently establishes a definite relationship between testicular hormone and pituitary action.

b.—If ossification of epiphyseal cartilages complete, the skeletal changes are characteristic of acromegaly.

Acromegaly may be engrafted on primary gigantism, resulting in an acromegalic giant.

B.—Characteristic skin—subcutaneous and visceral changes.

(The above symptoms have been described as due to over-function of the anterior lobe.)

2.—Hyperglycemia and glycosuria—

There is experimental evidence that stimulation of the posterior lobe produces hyperglycemia and glycosuria in animals.

Furthermore, glycosuria may be present during active stages of pituitary gigantism and acromegaly.

II.—Under-function (hypopituitarism).

1.—At puberty—

Skeleton takes on feminine form and also in males there is little or no beard and feminine distribution of pubic hair. In females likely to be absence of axillary and pubic hair.

2.—Before puberty—

Failure of development of external and internal genitalia, resulting in some degree of sexual infantilism.

3.—After puberty—

Diminished sexual activity or complete loss with impotence or amenorrhea.

Identical skeletal and genital conditions can be produced in dogs by partial anterior lobectomy.

(The above symptoms have been described as due to decreased function of the anterior lobe.)

4.—Before full stature obtained—

Bones do not develop to normal size. Result is a fairly normally proportioned dwarf.

On this point there is considerable doubt. Dwarfism is probably not due to disturbance in the pituitary alone.

5.—Adiposity, whether onset before or after adolescence.

6.—Increased sugar tolerance.

7.—Drowsiness and mental dullness.

8.—Asthenia and lowered body temperature.

9.—Hypotension.

10.—Polyuria—

At present weight of evidence in favor of lesion of posterior lobe, either direct or by pressure, as cause of diabetes insipidus.

11.—Epilepsy—

A certain number of epileptics are found among adipose hypopituitary cases where there is no evidence of tumor.

(The above symptoms have been described as due to decreased function of the posterior lobe.)

12.—Fröhlich's syndrome—

Adiposity associated with genital infantilism. Condition has been produced in animals by removal of posterior lobe and part of anterior lobe. Clinically the condition is one of hypopituitarism.

III.—Dyspituitarism—

Theoretically various combinations of over- and under-function of both lobes are possible. Any combination may begin before or after puberty with different results. Furthermore, hypofunction may follow hyperfunction of the same lobe.

IV.—Polyglandular syndromes—

The problem of disordered pituitary function is sufficiently complicated in itself, but becomes even more intricate by the tendency of other ductless glands to enter into the picture.

V.—In regard to pituitary, apart from the clinical signs enumerated, there are certain procedures which may give valuable aid. As for example:

- 1.—Signs and symptoms of brain tumor.
- 2.—Wassermann.
- 3.—Visual fields.
- 4.—Sugar tolerance.
- 5.—Basal metabolism.
- 6.—X-ray of sella turcica.
- 7.—Blood pressure.
- 8.—Temperature changes.
- 9.—Careful kidney studies.

The subject of pituitary gland therapy is certainly one about which the profession needs more information, and especially information which is both detailed and accurate. For this reason it is to be hoped that in dealing with such cases clinicians will emphasize the following points:

1.—Careful and detailed clinical and laboratory study for the purpose of detecting evidences of disturbed gland function. Such studies are particularly necessary in cases where there may be disturbances in more than one gland.

2.—The use of gland products with special reference to the clinical symptoms. Up to the present practically no therapeutic effects have resulted from the use of the anterior lobe of the pituitary alone and the effects from the use of the posterior lobe have not been encouraging. Generally speaking, where results have been obtained the whole gland has been used. It would be of interest to collect more data on the therapeutic use of separate portions of the gland.

3.—In general the use of the pituitary gland products alone rather than in combination with other glandular products. This suggestion is made in order to procure more accurate therapeutic information. Certainly very little is to be learned from the use of hit or miss polyglandular products.

OVARIAN GLAND THERAPY.

By FRANK A. PEMBERTON, M.D., BOSTON.

To obtain a clear idea of the present status of ovarian gland therapy it is wise to review some of the facts regarding the source, action and preparation of the material used in the treatment.

It has been practically proved that the cells

of the corpus luteum and the theca cells of the Graafian follicles, especially the atretic ones, manufacture the secretion. It is probable that there are interstitial cells in the stroma of the ovary that also supply the secretion. The presence of these cells in sexually mature ovaries is denied by some (Myer, Frankl), and though declared to be present, their secretory activity is thought to be slight by others (Fellner).

The isolation of the exact secretion chemically has not been satisfactorily proved up to the present. Fellner has isolated what he terms a sexual lipid from the corpus luteum, interstitial cells, and placenta, which experimentally causes enlargement of the uterus, vagina and breasts, but does not influence menstruation. Herrman has isolated a somewhat similar one, Seitz also. Wintz describes two substances from the corpus luteum which appear to have opposite effects on the blood pressure, coagulation time, and bleeding from the uterus. There is no unanimity of opinion, however, as there is in regard to the internal secretion of the adrenal and thyroid.

It is thought by some that there is more than one secretion with somewhat different effects. Theoretically, extract of corpus luteum is supposed to inhibit menstruation because of the large, permanent corpus luteum found in pregnancy, and its use is accordingly advised in excessive bleeding, while extract of the whole ovary and of the ovary without the corpus luteum are used for decreased menstruation and amenorrhoea. Opposed to this is the experience of many that corpus luteum and whole ovary extracts appear to have the same effect on abnormal bleeding. Graves' suggestion that, as the different cells which manufacture the secretion have the same embryological origin, it is probable that their secretions have the same qualities, is reasonable and is borne out by clinical experience.

A great difficulty in this therapy is that the manufacturers have no common process for producing the preparations which are used, and there is no means of standardizing them. The tissue of the glands of internal secretion is said to deteriorate more rapidly than other tissues, so the manufacture should take place immediately after removal. The ovarian preparations, except those put up in ampules, seem to deteriorate in time and should be used comparatively soon. The corpus luteum extracts appear to do this earlier than the others. This deterioration is probably a decomposition which shows its presence by a digestive upset in the patient.

The preparations used are an extract of the whole ovary; an extract of the ovary with the corpus luteum previously removed, called ovarian residue; and extracts of the corpus luteum alone. They are put up in capsules of the powder, in tablets, and in ampules, the last being reserved mostly for corpus luteum extract in this country.

The mode of action of the preparations is not definitely settled. It may be simply a stimulative action on the ovaries and other glands of internal secretion which appear to be closely related to the ovary, the thyroid, adrenal and hypophysis. It may be a substitute for an entire lack of ovarian secretion, as after castration, but this action does not appear to be as definite as in the case of thyroid extract used in cretinism. Esch thinks the action is so unspecific that it may be explained as a reaction against a protein. He has had suggestive results in treating menstrual disturbances with human milk protein given subcutaneously, getting effects similar to those following ovarian organotherapy.

On the whole it is probable that the effect is a stimulating or balancing effect on the internal secretory organs with some substitutive action.

From this review it may be deduced that there is no settled method for using ovarian preparations. They are all being tried for all the various diseases without bringing any one of them strikingly to the fore for any particular disease. Attempts are being made to increase their efficiency by combining other gland therapy with them in cases which show derangement of two or more glands.

The characteristic symptoms for each gland and combinations of glands are gradually being worked out. It must be remembered in all organotherapeutic treatment that more than one gland may be at fault.

They are perhaps most useful in treating the symptoms of the menopause, the hot flushes, nervous troubles and high blood pressure. It is generally acknowledged that all three preparations are valuable, but that the whole ovary and residue are more efficacious than the corpus luteum. The hot flushes, which is the symptom that the patient complains of most, are relieved to a great extent and in a good many cases stopped. The general condition is improved, showing that there may be a tonic effect. In the artificial menopause, following castration, the effect is more prompt and decided than in the natural menopause. The symptoms following castration may be avoided to some extent by starting the ovarian extract before operation. This may be advisable in the nervous, high strung, thin type of woman.

There are cases of high blood pressure occurring at the natural menopause which show no organic lesion, such as cardio-renal disease. Ovarian extract here seems to lower the blood pressure in some cases, but must be kept up in large doses for some time to obtain the effect.

Menstrual irregularities, such as delayed catamenia; slight bleeding before and continuing after the usual menstruation; clotting and temporary functional amenorrhoea are all favorably influenced by ovarian therapy, bringing about a normal cycle.

There are some cases of headache of the migraine type occurring at menstruation only and

disappearing at the menopause, which give brilliant results with the use of ovarian therapy. The residue or whole ovary is used.

Menorrhagia and metrorrhagia must be of the internal secretory type to be influenced by this therapy. If there is any definite pathology, such as fibroids, polyps and pelvic inflammation, organotherapy is not indicated. There are a good many reports of the successful treatment of the bleeding at puberty and the climacteric treated by this method, the most promising being those from Germany, where the preparation is given more often intravenously than here. It is in these cases that many recommend corpus luteum extract especially.

Amenorrhoea of a permanent type, coming on with a progressive decrease in the amount of menstruation or characterized by only occasional periods, is not so amenable to this treatment. It must be kept up for a long time in rather large doses. If the patient is putting on weight rapidly it may be wise to add thyroid extract to the ovarian. They may menstruate more often under treatment, but are not likely to have the normal menstrual cycle re-established.

The treatment of essential dysmenorrhoea, where there is no pathological condition except mal-development of the uterus, is fairly successful in relieving the discomfort and increasing the amount of flow in a good many cases. Here again the reports from Germany under intravenous administration are more promising. It is generally acknowledged that the residue and extract of the whole ovary are more efficacious than the corpus luteum.

The value of ovarian therapy in sterility is not definitely established, but it is used in those cases which complain of amenorrhoea and dysmenorrhoea.

It is recommended in the vomiting of early pregnancy, but the reports of its results are conflicting. Here extract of corpus luteum is used on the theory that the vomiting is due to an undersecretion on the part of the corpus luteum of pregnancy. From the same point of view corpus luteum is administered to cases having successive miscarriages without demonstrable cause. Not enough work has been done to determine its value.

Ovarian therapy is recommended for lactation atrophy, infections such as kraurosis and furunculosis of the vulva after the menopause, on the theory that it increases the blood supply to the parts; mild cases of hyperthyroidism, as the ovary is believed to be antagonistic to the thyroid; and in chlorosis combined with the usual treatment.

We think it fair to conclude that ovarian therapy is valuable, but it is not established on a sound basis as yet, because the actual secretion has not been isolated; the preparations are not standardized as to strength; and they deteriorate fairly rapidly.

DISCUSSION.

Dr. J. C. AUB: Throughout the evening, a discussion of the interrelation of glands of internal secretion has been avoided. The impression from the symposium has been discouraging as to the present value of the use of these various glands in treatment of true endocrine disorders. I think it ought to be brought out that there is the added difficulty of diagnosis, which is increased because most cases present not a defect of one gland but of several.

The basal metabolism, which is the only good functional test for the internal secretions, demonstrates this difficulty. It is affected not only by the thyroid gland, but also somewhat by disturbances of the gonads and pituitary, though very possibly these last two produce the effect by means of an interrelation with the thyroid. On the other hand, the adrenal gland seems to be an independent mechanism and may cause fluctuations of short duration, probably through its secretion—adrenaline. This, therefore, suggests the complexity of their activities, and the difficulty of determining which gland is primarily at fault in disease. While the relationship of these glands to each other is not clearly understood, we cannot give adequate treatment.

Dr. W. B. CANNON: Dr. Aub asked about the importance of knowing the interrelations of these glands. I have no doubt whatever that they are very intimately interrelated. We have good evidence in some instances of the way in which the destruction, or overaction of one gland will affect another, but the relations are highly complex. We must learn about them, however, before we shall have a thoroughly rational mode of taking care of complicated endocrine disorders.

Dr. Lawrence spoke of using the whole adrenal gland. It is a double gland and he is, therefore, using two substances. I suggest he be bold and separate the double gland into its parts and see what each one will do by itself. Then we would know from what he gets his results. I would make the same suggestion to Dr. Ohler. He is using the whole pituitary. There are, perhaps, three glands, certainly two, in the pituitary, and it might be well for him to try using each part.

EPIDERMOPHYTOSIS.*

By ARTHUR M. GREENWOOD, M.D., BOSTON
Assistant Dermatologist, Massachusetts General
Hospital.

THE frequent references to epidermophytosis which we are now seeing and its great prevalence, I believe, warrant this brief sketch of the disease and of its laboratory investigation. The condition is undoubtedly frequently seen by the general practitioner and usually classed with the eczemas, the fact not being recognized that it is parasitic and contagious, extremely difficult to eradicate, and always a potential source of infection to others, besides being exceedingly uncomfortable and often crippling to its possessor.

Epidermophytosis is a form of ringworm. The disease ringworm or tinea includes ringworm of the scalp, tinea capitis; ringworm of the beard, tinea sycosis; tinea circinata, a

superficial, ephemeral ringworm of the glabrous skin; ringworm of the nails; and epidermophytosis, or eczematoid ringworm, and in discussing the last we exclude from consideration all the others.

The fungi causing these various forms of the disease belong to three genera: Microsporon, Trichophyton, and Epidermophyton. Strictly speaking, the name epidermophytosis is not correct, implying as it does that this form of the disease is always caused by some species of the Epidermophyton. That this genus was always the cause was the original conception, but recent work has shown the genus Trichophyton in a large proportion of the cases. However, the name epidermophytosis has thus far been retained since it embodies our concept of the disease as distinguished from the other forms of ringworm. This concept is as follows: A chronic, contagious, fungous disease of the skin; highly resistant to treatment; at times to be seen on practically any part of the body, but involving most commonly the hands, feet, groins, and peri-anal region, less often the axillae and under the breasts, all locations where there are heat and moisture, factors favorable to the growth of the fungus. Subjectively, it is usually pruritic, at times excessively so, but practically never negligible from the patient's point of view if the process is at all active.

The form of the disease known as tinea cruris or eczema marginatum was described as early as 1869 by Hebra, but the other forms are of much more recent recognition. The following is a very brief clinical description of the more common forms of the disease.

On the feet it ordinarily manifests itself as a maceration of the skin at the depths of the interdigital spaces, most often between the little and fourth toes. At times macerated hyperkeratotic masses can be shelled out, the so-called soft corns. From the interdigital spaces there may be extensions onto the plantar and dorsal surfaces of the feet, made up of deep vesicles with steel-blue centers and collarettes of fine scales where these vesicles have broken and dried. Very commonly the nail of the little toe is infected and is opaque, softer than normal, thick and irregular, and other nails may be involved. This form ordinarily gives rise subjectively only to occasional itching, but in warm weather or after much walking in shoes and socks which do not allow sufficient aeration the fungus becomes active, the vesicles break out, sometimes becoming bullous on the balls of the toes, and there is severe itching. Another form found on the feet is the hyperkeratotic, in which are seen peculiar yellowish keratotic areas on the soles or heels, not necessarily at points of pressure.

The form of the disease known as tinea eru

*Read in part before the Worcester District Medical Society.

ris or *eczema marginatum* is undoubtedly familiar to most physicians. It occurs on the inner surfaces of the thighs in the crural region and may extend downward or onto the scrotum and penis and backward over the perineum to the peri-anal region. It manifests itself as a rather dark red, circular area whose border usually shows many fine vesicles, and whose center does not clear as does the ordinary *tinea circinata*. The surface is rather moist and papular and shows delicate scaling. In the perianal region there is usually some whitish, sodden, macerated epithelium to be seen on a reddened base. Subjectively there is a stinging, burning sensation rather than a real itching, but in the peri-anal region there may be a marked pruritus.

The disease, as it affects the hands, consists of persistent and recurring attacks, lasting over many years, of areas of erythema with scaling, infiltration and fissuring, and always at some time showing the characteristic deep vesicles, usually at the advancing margins. Its most common location is on the backs of the hands, extending onto the webs of one or several fingers. There is involvement of the contiguous finger surfaces, oftenest of the proximal phalanges, but at times extending to the tips and involving the nails. The so-called washerwoman's *eczema* is probably a fungus infection, and recent work has shown certain yeasts to be the infecting organism in some cases rather than the genera with which we are concerned.¹ All these fungous infections of the hands have for years been diagnosed as *eczema*, and we are seeing in our clinics cases which years ago were so considered, which have been relieved, but which recur year after year. It is not improbable that all cases of *eczema* of the hands may be due to fungi, excepting dermatitis from external irritants, infantile *eczema*, and those of pyogenic origin.

These are the chief and most common forms of epidermophytosis. On other parts of the body they are less distinctive and usually a clue to their origin is to be found in a primary, typical focus on one of the commonly involved regions.

The disease is astonishingly prevalent and apparently increasingly so. In 1919, at the Skin Department of the Massachusetts General Hospital, there were diagnosed 55 cases, including those of *eczema marginatum*, out of a total of 4065 new patients. At present we see each day at least one new case, frequently four or five, and it should be borne in mind that these are only the ones which are giving symptoms sufficient to bring the patient to the hospital. In a series of 50 patients who came with other troubles one out of two showed evidence of the disease, ready to light up, given the proper conditions, and, what is most im-

portant, each one a potential source of infection. Nor is this a disease of the unwashed outpatient. One of the staff at the Massachusetts General Hospital finds it fourth in frequency among the diseases he sees, being outnumbered only by acne, *eczema* and alopecia. It is very prevalent among students and gymnasium frequenters, one of the popular names for *eczema marginatum* being "jock strap itch," undoubtedly indicating an accurate observation as to one source of infection. In these gymnasium cases it seems probable that the mats and floors of the showers may be sources of infection. In some cases laundries seem to be implicated, and we have several times seen an acute attack follow the doing of a washing in which presumably some of the clothes were infected. Recently we have seen a very acute case which came on immediately after wearing an old pair of gloves while covering with asbestos preparation a hot steam boiler. The combination of wearing the probably infected gloves with the heat and moisture incident to the work brought on the sudden, universal infection of both hands. It is quite possible that the fashion of wearing heavy wool socks in recent years is responsible for part of the increase in this disease, since such hosiery not only keeps the feet moist and warm but also cannot be sterilized by boiling.

LABORATORY INVESTIGATION.

The cultivation and identification of parasitic fungi, or even their microscopic discovery in the scales and hairs, is always a matter involving time and patience. For some reason the usual clinical manifestations of these mycotic affections are out of all proportion to the amount of fungous growth found, and it very often is a matter of long and careful search before the parasite is discovered. Naturally a negative result in such cases leaves one uncertain whether the fungus is really missing or only missed.

It is possible that much of the clinical manifestation of these diseases is in the nature of a trichophytide, which (like the tubercle) may be a manifestation in a sensitized skin of the presence of the fungus elsewhere on the body. An interesting discussion of the trichophytide is to be found in Bloch's article.² The laboratory end of the study of these mycoses resolves itself into two parts: (a) The examination of the fresh material—scales, hair, or nails; and (b) the cultivation and identification of the fungi.

Examination of the Fresh Material.—(1)

Selection of Material. (a) In the macerated interdigital foot cases the best material will be found at the advancing borders of the lesion. In practically every case there will be seen at the junction of the eroded and macerated area

with the normal skin a delicate sealy border, with the unattached end of the desquamating epidermis toward the lesion. If this edge is raised with forceps and gently peeled off toward the normal skin it will most often be found to contain the parasite. The white, macerated material, in my experience, is useless for microscopical and cultural purposes since it is loaded with contaminating pus organisms and saprophytic fungi. These directions also apply to the cases of *trinea cruris* or *eczema marginatum*.

(b) The vesicular type. If seen very early in the vesicular outbreak, one should cut off the roofs of some of the vesicles and invert them on the slide so as to examine their under surface. It is a peculiar fact that not all the vesicles so examined will show the parasites, no matter how carefully the examination is made. As far as I know, there is as yet no way of telling from their clinical appearance which vesicles are infected. It is possible that only the early lesions will be positive. Only within the past two weeks have I seen a case in which every vesicle examined was positive, and that was a very acute and extreme case involving both hands, with marked trichophytides on other parts of the body. Mitchell of Chicago, in his recent article on the subject in the *Archives of Dermatology*,³ states that the brownish, dried vesicles yield him the best results, and my experience agrees with this, especially in the older cases. Sometimes the desquamating collarettes left from this vesiculation will be positive. Crusting and exudative material is of no value, nor are the parakeratotic scales which are often seen.

(c) In the nail cases it is well to scrape the surface with a glass slide and from this cleaned surface to pare thin pieces with a knife. The scrapings with glass are beautifully thin and one is tempted to use them, but they are not of much value because the fungi do not grow in one stratum, and too thin scrapings may only show them in section, when they are unrecognizable.

Having taken the material to be examined, it is the best procedure to keep it between two glass slides whose contiguous surfaces have been flamed. These can be held by a rubber band and marked with a colored pencil for future identification. I believe the slides are superior to envelopes or paper containers since it is much easier to cut up and manipulate the scales in planting when they are on a glass surface; the scales often stick to the paper containers and it is difficult to remove them with as little handling as in the use of slides; and then, too, the paper containers are never sterile.

After the material is collected it may be kept almost indefinitely before planting, and

a certain amount of delay is advantageous since it may eliminate many of the bacterial contaminations. An exception to this statement arises in the case of the examination and planting of fresh vesicles. These should be planted and examined immediately. The roofs of vesicles when dried are much more frequently negative than fresh ones from the same case.

For the microscopical examination of the material, use is made of the clearing effect of *KoH* or *NaOH* on the tissue cells, while the fungi are resistant, the result being that the fungi show as refractile bodies against a fairly clear background. The disadvantage in the use of *KoH* is that in a comparatively short time, depending on the strength used, the fungi are affected also, so that for permanent preparations some other clearing solution is necessary.

For rapid work a 40 per cent. aq. solution of *KoH* is used and the slide very gently heated. By this method scales may be examined in a few minutes. For slower clearing and more permanent preparations which will keep for about ten days one may use equal parts of a 30 per cent. solution of *KoH* and glycerine. This should be heated also, and scales are well cleared in one or two hours if not too thick. This is the method of choice unless permanent preparations are wanted.

For permanent preparations which will last for six months to a year, or perhaps slightly more, we use

Lactic acid	1 part
Phenol	1 part
Glycerine	2 parts
Distilled water	2 parts

This clears quickly and well, its only disadvantage being a tendency to the formation of very fine, long crystals which might deceive the beginner when searching for the fungi.

These permanent mounts have to be ringed with a cement, and by far the most satisfactory for this or any similar purpose is one made by Professor R. E. Schnh, Howard University, Washington, D. C.

Before clearing scales it is always wise to remove the fat by washing with ether. The *KoH* on a scale which contains much fat gives rise to many refractile globules which may be very deceptive and may make one think they are mycelial fragments. These globules, however, vary a great deal in size—much more so than mycelial fragments ever do. The *KoH* also affects many of the epithelial cells, so that they appear crowded with spores; an appearance which should not deceive the investigator, since these fungi do not penetrate the cells and do not form spores in the human host.

Having mounted and cleared the specimen, one searches with patience for the parasite,

which should appear as a refractile septate strand—sometimes branching, and sometimes broken up in a chain of fragments. Often separate fragments or bodies resembling them are seen, but one should never make a positive diagnosis on one or more fragments unless they are found in chains. These fragments are commonly spoken of as spores, but most authorities agree that they are not true spores but fragments of the hypha or vegetative part of the fungus.

The high dry lens of the microscope should be used, with much of the light cut off, and since the scales are usually quite thick one must examine all levels by focussing up and down. When expert, the fungi can frequently be picked up with the low power, which is a great saving of time, but in all cases, before pronouncing a case negative, several hours should be spent in careful search.

There are various staining methods which have been used to demonstrate the fungi in scales and hairs. Personally I do not use any of them for the ordinary clinical work. They take much more time than the methods just described, and are uncertain and rather unsatisfactory in their results. Practically their only advantage is in the making of permanent preparations, and even in the best preparations there is a certain amount of distortion so that the picture is not the same as that of the fresh specimen.

All the fungi show two stages of growth—the simple vegetative, and the form in which certain portions of the hyphae are differentiated for the purpose of reproduction. The primary reproductive body of the fungi is called a spore, and in the fungi it performs a function analogous to that of seeds in the higher plants. The vegetative forms are practically all alike—certainly not sufficiently different to allow identification of the different genera and species in the scales or hairs, so that the manner of producing spores or fruiting bodies is the chief means at present known for such identification. The reason for this short excursion into mycology lies in the fact that in the host the fungi show only their vegetative form, and in order to discover their manner of spore production and other distinguishing features they must be grown outside the host. This, then, is our reason for cultivating these organisms, to allow of their identification and classification, and to correlate if possible the various genera and species with definite clinical manifestations. Such work has not advanced very far. The mycological classification is still very hazy and the differences between many species are slight. One other mycological detail must be mentioned before considering the culture media. On the media containing sugars most of these fungi, after a varying length of time, take on

the so-called pleomorphic form, which is a return to the vegetative manner of growth. This shows as a white, fluffy overgrowth of hyphae, which do not produce spores, and transplants from which always show this same pleomorphic growth, never the characteristics of the original culture. On this account all cultures have to be grown on two media, one containing carbohydrate to show the fructification, and the other, without carbohydrate, to preserve the culture from the pleomorphic change.

All these fungi show different manners of growth on different media, and the following were devised by Sabouraud in Paris as international proof media, so that results in different countries might agree. Unfortunately the war interfered with the production of the French sugars used, so that work is now being done in this country to find what sugars can be used with the same result.

Sabouraud's media were as follows:

(a) Glucose	4%	(b) Maltose	4%
Peptone	1%	Peptone	1%
Agar	1.5%	Agar	1.5%
and (c) The conservation media			
Peptone	3%		
Agar	1.5%		

The French glucose and maltose are no longer obtainable, but it has been found that for practically all purposes American pure dextrose (Difco) will do. French peptone (Peptone Chassaigne) is necessary in growing certain fungi on account of its acidity, and it is still available.

The ingredients are mixed as usual in making media, and sterilized, care being taken not to overheat in the sterilization as this changes the sugars. Short fractional sterilization is the best method. For the first plantings of the original material slants in tubes are used. For further study of the growths obtained plants are made in Erlenmeyer flasks, which give more material and space for the fungi to show their characteristic manner of growth. Petri dishes may be used, but they do not give a sufficient depth of media, and contaminations are apt to creep in at the edges. The water of condensation which collects on the cover also interferes with inspection and photography of the growth.

In making the first plants the dried scales are cut up into very small pieces and planted on the agar, about four pieces to a tube. At least 20 plants should be made in each case, but often as many as a hundred are necessary before getting a growth. The great obstacle to pure cultures is the presence of pus organisms and saprophytic moulds. Various methods have been used to inhibit these, such as flaming the scales, washing in alcohol, putting gentian violet (1:500,000) in the media, etc.,

but none of these are very satisfactory. Contaminations are the great bane of this work.

The cultures are grown at room temperature. After obtaining a growth it is transplanted to the three different media and its growth on each is compared. It is grown in hanging drop preparations of glucose bouillon, and direct mounts are made and mounted in glycerine for study. The authoritative work on this subject is by Sabouraud.⁴ Unfortunately our results do not always check up with his, partly because our media differ, and partly, also, because we probably have a different flora in this country.

This part of the subject should not be left without warning any who may be interested that the results, especially of the cultures, are distinctly discouraging compared with the amount of time and patience expended. Personally, after nearly two years' work I am unable to get growths in more than one out of four or five cases investigated—that is, of the cases in which the skin is affected. In practically every case of ringworm of the scalp the fungus can be grown. The work is important, however; it offers practically a new field and can be carried on in spare moments and without the necessity of elaborate laboratory paraphernalia.

TREATMENT.

In marked contrast to *tinea circinata*, epidermophytosis is ordinarily very resistant to treatment, and it is difficult to explain why an organism which exists in the host only in its vegetative form should be able to resist for so long parasitoidal applications, or why it should so frequently recur in its original site long after all traces have apparently disappeared.

Probably the application most commonly used in this country is Whitfield's ointment. The formula for this as given in the latest edition of Whitfield's book is:

Acid benzoïc	gr. XXV
Acid salicylic	gr. XV
Parathini molli	5 II
Ol. coccois nuciferae	ad 3 I

Most dermatologists in this country use it somewhat stronger than this, even up to 12 per cent. and 18 per cent. of the salicylic and benzoic acids respectively. To a certain extent this ointment may be used as a therapeutic test, since dermatoses resembling epidermophytosis are quite apt to be made much worse by its use. A certain number of bona fide cases of the disease are, however, much irritated by Whitfield's ointment, so that the test is not decisive.

In France, chrysarobin in one per cent. strength is used more than in this country. Its drawbacks are its staining properties and its severe irritant action if not used with precaution. There is no doubt, however, that it

is a valuable application. It may be used in an ointment or painted on in liq. gutta percha.

Whitfield recommends for the resistant foot cases:

Chrysarobin	3 I
Ether sulphurici	
Acetone	aa 3 IV ss

painted on during the day, and the benzoic and salicylic acid ointment at night.

Iodin undoubtedly has stronger parasitoidal effect on these fungi in vitro than any of the other substances employed. When used clinically, however, it is far from being infallible. It is used as the tincture, painted on; in ointments, 5 per cent., goose grease being the best excipient.

Dr. E. Wood Ruggles⁵ reports success from the use of this ointment:

Zinc Oxide	6.
Unc. picis liq.	12.
Phenol	1.
Unc. Aq. Ros.	18.

followed, after the eruption has well subsided, by

Tinct. Iodi.	4.
Spir. Camph.	ad 28.

Other methods are 1:5,000 potassium permanganate soaks or hot fomentations for 15 minutes three times daily—combined with Whitfield's ointment. Saturated aqueous solution of pieric acid painted on twice daily for a week. This should not be used continuously for longer than this on account of danger of absorption.

The x-ray has been used with some success and seems to act by modifying the skin so that it is no longer favorable to the growth of the fungus. The x-rays are not directly parasitoidal.

Ultra-violet ray therapy acts favorably in a certain number of cases, probably because of its desquamating effect.

AUTOMOBILE EXHAUST GAS AS A HEALTH HAZARD.*

By VANDELL HENDERSON, PH.D., NEW HAVEN, CONN.
Laboratory of Applied Physiology, Yale University.

WITH every advance in industry and the arts there is liable to be associated some new physiological strain or health hazard. This has been

*A paper read before the Harvard Medical Society, January 24, 1922, and before the American Climatological and Clinical Association, May, 1922.

true of machinery, of the chemical industries, of electricity, and it is now proving true of man's latest and most widely used utility, the automobile. As a rule, however, the hazard has been confined to some particular group of workers or class of persons. The risks involved with the automobile are, however, almost universal. The loss of life in accidents as reported in the daily papers is so common that it is receiving serious attention, although not yet very effective measures of amelioration,—as everyone knows.

But it is not very generally realized that the exhaust gas from automobiles constitutes scarcely a less serious health hazard. Fortunately, however, engineers are beginning to recognize that the sanitary side of large public undertakings, and even of some private developments, deserves study, and the public is learning to expect this protection. Accordingly, when plans were made for the construction of the first long vehicular tunnel in this country, these plans included extensive investigations of the basic facts necessary to the ventilation of such a tunnel, so as to render it not only safe but practically innocuous to its passengers. This is the more important as such tunnels will probably, to a considerable extent, replace bridges in future, both because of their cheaper construction, and because they do not obstruct the waterways.

The Commissions of the States of New York and New Jersey, charged with the construction of the vehicular tunnel, or rather tunnels, under the Hudson River, arranged with the United States Bureau of Mines to undertake these basic investigations. The work was divided into several special problems, of which we need here consider only two, namely: (1) the amount and chemical composition of the exhaust gas produced by various cars under various conditions of speed, load, and temperature; and (2) the physiological effects of the substances in exhaust gas, and their allowable amounts not involving appreciable ill effects when such gases are breathed.

The first of these problems was placed in the charge of Mr. A. C. Fieldner, at the Bureau of Mines Experiment Station, in Pittsburgh. An extensive investigation was carried out by him and his collaborators, and has shown that to a large extent the deleterious character of exhaust gas of automobiles arises from the tendency of drivers to adjust carburetors so as to afford a maximum of power, rather than to utilize fuel with the maximum efficiency.¹ The gasoline mixtures used are generally much richer than would be best both from an engineering and sanitary standpoint. More flexible carburetors and greater use of the adjustments, so as to attain the required speed and power with a minimum of fuel, would not only

result in reducing the waste of gasoline, but in an exhaust gas distinctly less injurious to health. These investigations show that approximately one-third of the fuel value of gasoline is wasted and that the carbon monoxide, the particular toxic constituent of exhaust gas, averages about 7 per cent. As regards the total quantity of exhaust gas produced, it is sufficient to say that most passenger cars, with the usual carburetor adjustment, produce from 1 to 2 cubic feet of carbon monoxide per minute.

The second problem above referred to was investigated by the writer with the collaboration of Dr. H. W. Haggard, Dr. A. L. Prince, M. C. Teague, R. M. Wunderlich, and a number of chemists for the analytical work, in the Laboratory of Applied Physiology in Yale University.^{2,3} Our investigations have completely confirmed the conception of Paul Bert, Haldane, and other investigators, that carbon monoxide does not form a permanent compound with the haemoglobin of the blood, but competes with oxygen. It has an affinity about 300 times as great; it is able not only to displace oxygen but to be again displaced by oxygen, when a person who has absorbed a certain amount of gas breathes pure air, or air enriched with oxygen. Our investigations also show that carbon monoxide has no other toxic characteristic except its combination with haemoglobin and exclusion of oxygen; it has no direct effect upon nerve cells; all of the nerve degenerations induced by carbon monoxide are due to this asphyxia. Dr. Haggard has, indeed, even succeeded in growing nerve tissue in considerable amounts of carbon monoxide.⁴ Animals, such as flies and other insects, which have no haemoglobin, are as entirely immune to any effect of carbon monoxide as they would be to nitrogen, the most inert of gases.

Our investigations show further that when gasoline, distilled from petroleum, is used, practically the only toxic constituent in the exhaust gas is carbon monoxide. When, however, benzol, and probably other related substances are present, as in some of the automobile fuels now sold, the amount of these substances escaping in the exhaust gas adds decidedly to its toxicity.⁵

Our investigations were carried out at first on ourselves and the other members of the investigating staff, in an air-tight room, lined with sheet iron. The data so obtained were later confirmed by large-scale experiments in which a dozen or twenty people at a time sat or moved about in a garage building in which a Ford car was installed. A drop of blood was drawn from a finger and analyzed colorimetrically for the percentage saturation with carbon monoxide; the pulse was counted; the volume of respiration measured; and the effect of exercise after running up and down four flights of

stairs, was noted. The Romberg test for steadiness was used in some cases.

The best of all indications proved, however, to be the headache induced by carbon monoxide. This is the characteristic oxygen deficiency phenomenon, observed in persons at great altitudes, and induced in nearly all persons by certain degrees of saturation with carbon monoxide, although there are some individual differences in the exact point at which it appears. It is usually of the throbbing frontal type, more rarely occipital. It easily passes into nausea and is accentuated by exertion.

Space forbids a detailed description of theory or experiments, but data were obtained sufficient to prove that the rate at which carbon monoxide is absorbed from air is such that at least an hour is required for the blood to attain a degree of saturation equal to half that which would finally be attained by a stay of indefinite duration.

From these demonstrations the following rule was derived for practical use: When the time is expressed in hours and the saturation in parts per 10,000 there will be no appreciable physiological effect when the product of the time multiplied by the saturation equals 3; when the product of time by concentration equals 6, there will be in some persons slight effect; when it equals 9 there will be in nearly everyone a distinct effect; when it equals 15 the condition is dangerous. An allowable vitiation, not exceeding 4 parts of carbon monoxide in 10,000 of air, is, therefore, recommended as a practical standard for vehicular tunnels.

It is quite certain that this standard is very often exceeded in garages. Severe headaches are extremely common among mechanics, and others, who work around automobiles; so much so that repeated partial asphyxia is a distinct health hazard.

The data given above will serve to indicate the character of the hazard in the small private garage. During the winter months in the northern States asphyxiations in such private garages are unfortunately quite common. The owner starts his car before opening the doors in order to get the engine warm. If the garage is 10 x 10 x 20 ft., giving a capacity of 2,000 cubic feet, and the car produces 1 cubic foot of carbon monoxide per minute, it requires only 1 minute for the vitiation which we have recommended for the tunnel to be reached; and in five minutes the atmosphere contains 20 parts of carbon monoxide in 10,000 of air, an amount sufficient to induce rapid asphyxiation. And, of course, if the car continues to run, the vitiation mounts steadily toward a rapidly fatal concentration of carbon monoxide.

In addition to our experiments on men, which could not, of course, be pushed beyond the point of severe headache, we have performed an extensive series of experiments on animals, which

we carried to the point of extreme, or even fatal, asphyxiation. These experiments were performed with pure CO, with exhaust gas from automobiles, and with illuminating gas. They show that CO is practically the sole toxic constituent in exhaust gas when pure gasoline is burned. Illuminating gas, however, owes, perhaps, 20 to 25 per cent. of its toxicity to some other constituent, perhaps benzol. Gasoline, as sold in some places, is mixed with coal distillate, which contains benzol, and produces a correspondingly more toxic exhaust gas.

Gasoline vapor itself has been found in our experiments to have qualities somewhat like those of ethyl ether.⁶ It is an anaesthetic, but the stage of excitement passes through a very narrow region of full anaesthesia into convulsions ended by death. In the toxicity of exhaust gas unburned gasoline is not an appreciable factor. Workmen are, however, sometimes overcome when they go into a large tank in which gasoline has been stored. Benzol is much more toxic, as Dr. Alice Hamilton has recently pointed out.⁷

Finally, these investigations have led on to the study of the treatment of CO poisoning. Obviously the first step in any treatment must be the restoration of spontaneous breathing, if it has stopped. For this purpose the manual prone pressure method of artificial respiration is to be recommended above any apparatus, for it is as effective, or even more effective, than apparatus, and it can be applied instantly, while the bringing and adjustment of apparatus involve delay. A delay of even a couple of minutes may sometimes be fatal.

The next step, after spontaneous breathing, must obviously be to accelerate the elimination of carbon monoxide from the blood. For this purpose the inhalation of oxygen has long been recognized as the specific procedure. But the difficulty arises that after a long exposure to an atmosphere containing carbon monoxide, respiration is very much depressed, and the inhalation of oxygen has no very stimulating effect upon the volume of breathing. It occurred to my associate, Dr. H. W. Haggard, and myself, to utilize the stimulating action of carbon dioxide. In a series of experiments on dogs we found that in animals which were brought almost to the point of death, and then allowed to recover spontaneously in air, the period of elimination of carbon monoxide from the blood covered several hours. When the subjects were made to inhale oxygen the rate of elimination was at first not very much more rapid, the reason being that the oxygen was inadequately inhaled. When, however, a small amount of carbon dioxide was added to the oxygen a very active breathing was induced, by which the lungs were so effectively ventilated, and the oxygen was given so free an op-

portunity to act upon the blood, that after a period of a quarter to half an hour nearly all of the carbon monoxide had been eliminated from the blood.⁸

Recently the American Gas Association, representing practically all of the illuminating gas interests of the country, has requested Dr. C. K. Drinker, of the Harvard Medical School, to organize a commission for the further investigation of the subject of resuscitation from illuminating gas poisoning. The members serving on this commission are, Dr. Drinker, as chairman, Drs. D. L. Edsall, W. B. Cannon, L. J. Henderson, W. K. Lewis, F. W. Peabody, Mr. C. B. Scott of the Bureau of Safety, Dr. R. R. Sayers of the U. S. Bureau of Mines, Drs. Howard W. Haggard and Yandell Henderson. The last two named have been appointed a sub-committee to investigate the efficacy of the above-mentioned treatment. Through the courtesy and coöperation of the Consolidated Gas Co., of New York City, which has placed at our service its emergency wagons, and with the support of Health Commissioner Copeland, and the hospital authorities of New York City, we have been able to give the method an extensive test. The results indicate that a deeply asphyxiated patient, who can be reached within a half-hour—and the utmost speed at this time is essential for success—and who is then given inhalations of oxygen containing 5 per cent. carbon dioxide, can be practically freed from carbon monoxide within 30 to 40 minutes. Frequently also consciousness returns.

The demand for cheaper gas on the part of the public, and the rise in the cost of crude petroleum, the introduction of the mantle burner, the increased use of gas for cooking and heating purposes, have inevitably resulted in an increased number of fatalities from illuminating gas asphyxiation. For those cases which can be reached in time the treatment above indicated will, it is our belief, not only increase the chances of survival, but also the probability of complete recovery and freedom from the distressing sequelae sometimes associated with poisoning by illuminating gas, or the exhaust gas of automobiles.

RUPTURE OF OVARY WITH MASSIVE HEMORRHAGE AS A COMPLICATION OF AN ACUTE APPENDICITIS.

REPORT OF A CASE, WITH REVIEW OF THE LITERATURE.

By HENRY S. PENN, M.D., LAWRENCE, MASS.

RUPTURE of an ovary with hemorrhage of various degrees may occur entirely independent of ectopic pregnancy. Such accidents are not only possible but are of much more common occurrence than we naturally imagine. The voluminous literature on the subject testifies to that effect. The possibility of serious hemorrhage was pointed out as early as 1851 by Nelaton,¹ Rokitsky¹ in 1855, and Pouch¹ in 1858, the latter calling it "ovarian apoplexy."

In addition, a number of cases were reported by Wilson,² who states that "there is a case on record of a woman who died from a shock on the eve of her marriage, as a result of a profuse intraperitoneal hemorrhage from a ruptured corpus luteum"; and similar papers by Hollins, Hind, Penny,³ Richard R. Smith,⁷ and a host of others. Schumann,³ in his recent review, brings the subject up to date.

The extent of the hemorrhage may naturally vary from a small amount up to a fatal exsanguination, as in the case reported by Pouch, where three pints of blood were lost.

The etiology of a purely ovarian hemorrhage is so far entirely hypothetical.

Jaile⁵ claims that rupture of small cysts of the ovary is a frequent cause of blood in the pelvis.

Schamberger⁵ found that hemorrhage was often due to rupture of utero-ovarian plexus of veins.

According to Primrose,¹ a sudden strain, a sudden rise in intra-abdominal pressure, especially if this happens a few days before or during the menstrual period, may act as the cause of the accident.

Novack³ maintains that the original site of Graafian follicle hemorrhage is the perifollicular stroma, and that it only later breaks into the follicle, and "in certain cases . . . the hemorrhage is of the perforative type, the blood breaking through the surface of the ovary, causing an abdominal hemorrhage" (Abstract of discussion, *Journal A. M. A.*, Vol. 77, page 695).

Richard R. Smith⁷ thinks that the cases of acute hemorrhage from a ruptured Graafian follicle or corpus luteum should be grouped by themselves, because they are apparently not caused by any pathological condition of the ovary or pelvic organs.

Schumann,³ on the other hand, points out that when a massive hemorrhage occurs from an ovary there is usually to be found some pathological process of the ovarian blood-ves-

sels present. This deduction is based on a case where the microscopic examination of the ovary did show degenerative fibrous changes of the blood-vessels.

In the author's case the hypotheses of Primrose and Novack seem to be well sustained, and as far as the literature could be traced this is the second case on record where an acute appendicitis was complicated by a ruptured ovary with massive hemorrhage. The first and almost identical case was reported by Primrose.¹

A preoperative diagnosis of this condition, while theoretically possible, is in reality a very difficult problem, especially in the presence of acute abdominal condition, as this case happens to be. However, two vital points are of practical importance in the diagnosis: First, early recognition of the hemorrhage and immediate operation; and second, to quote Bovee,⁴ "that from the personal as well as from the medical legal standpoint, a diagnosis of ectopic pregnancy should not be made in cases in which pregnancy should not exist" (Bovee quoted by Schumann³).

CASE HISTORY.

Present Illness.—Woman, age 20, married one month. Has always been well except for an occasional pain in the right side. The present attack began about five hours ago, with severe abdominal pain and persistent vomiting.

Physical Examination.—Pulse, 120. Temperature, 100°. There was marked tenderness and spasm over the right lower quadrant, otherwise negative. White count, 14,000. Vaginal examination disclosed nothing abnormal. A diagnosis of acute appendicitis was made and operation advised, which was refused. About 3 o'clock in the morning, next day, a hurried call was sent and patient was found in bed, pale, weak, with a feeble and thready pulse and in almost complete shock. She complained of a great deal of pain, headache and dizziness. Abdomen was somewhat distended, pain all over, but more so over the right lower quadrant. Temperature, 100°. Pulse, 136-140.

Operation.—Right rectus incision. Free and clotted blood escaped upon opening the peritoneum. Bleeding seemed to come from pelvis. Appendix found markedly injected and kinked. Incision enlarged downward and uterus brought into view. Right ovary found to be the source of hemorrhage. It was normal in size, somewhat twisted on its pedicle, and presented a ruptured Graafian follicle, from which active bleeding took place. Ovary and tube were removed, also the appendix. Abdomen cleansed of blood, which amounted to about 11 to 12 ounces. Small rubber drain inserted and wound closed in the usual manner. Patient made an uneventful recovery.

Conclusion.—Apparently in this case, like in the one reported by Primrose, the hemorrhage was due to the increased intra-abdominal pressure brought about by the persistent vomiting. It is also worth noting that the patient's menstrual period took place a day after the operation.

Pathological Report.—Received ovary, tube and appendix. Tube is slightly thickened, dark red in color, and shows fibrous serosal adhesions. The ovary is pale, normal in size, and shows an area of rupture on surface communicating with small cavities, which can be stretched open to a distance of 1 cm. The appendix measures 7 cm., pale, with fibrous thickened wall and dilatation of the terminal one-half of the lumen.

Microscopic examination of ovary shows luteal tissue and area of hemorrhage; probable source of intraperitoneal hemorrhage. Fallopian tube shows extreme congestion of vessels, with slight infiltration of wall with polymorphonuclear leucocytes. The mucosa shows no pathological change.

Diagnosis.—Corpus luteum and hemorrhageum. Acute congestion of tube. Chronic fibrous appendicitis. (Pathological Department, Tufts Medical School.)

POSTERIOR RESECTION OF THE RECTUM AND RECTOSIGMOID (KRASKE OR MODIFIED UNDER REGIONAL ANESTHESIA).

LARLEY, G. L. (*Johns Hopkins Hospital Bulletin*, April, 1922), discusses his method of performing the operation for resection of the rectum under local anesthesia, recapitulating as follows:

1. The choice of the method of anesthesia is one of the most interesting problems connected with the surgery of the rectum and rectosigmoid.
2. Most of the postoperative complications may be attributed to inhalation narcosis, especially ether, and

can be avoided or considerably lessened by the use of regional anesthesia.

3. Regional anesthesia does not increase the resistance of the patient, but leaves the vital functions of the body in the same condition.

4. The anesthesia does not prevent pulmonary embolism, but excludes the danger of pulmonary post-operative complications, provided no acute condition exists at the time of the operation.

5. The anesthesia has no ill-effects on the gastrointestinal tract; thus the possibility of paralytic ileus and the tendency toward hemorrhage are reduced.

6. All patients are amenable to the method, but one should be cautioned against borderline cases.

7. Previous conditions, such as chronic lesions of the heart, with or without compensation, high blood pressure, pulmonary tuberculosis, diabetes, at least mild and chronic, easily controlled by dietary measures, and chronic renal conditions do not seem to interfere with the operative prognosis.

8. The use of morphin and scopolamin controls the psychic state of the patient and greatly contributes in establishing favorable conditions during the operation; but the stage of twilight sleep must not be reached.

9. With the abdominal field block procedure, colostomy is performed painlessly, provided the patient is not too obese and the mesocolon is not too short. Exploration is possible in the majority of cases, if gentleness is used.

10. The sacral block, consisting of the caudal or epidural and trans-sacral block, added to the paravertebral block of the last three lumbar nerves on both sides, constitutes the method of choice for the posterior resection of the carcinomatous rectum and rectosigmoid.

11. The administration of the anesthesia is not difficult, but it requires practice and patience, irrespective of the gentleness which must always be used in handling conscious patients.

12. If the anesthetic does not give complete anesthesia throughout the operation, the administration of a first stage ether anesthesia during the deep manipulations constitutes a combined method much safer than general narcosis alone.

[J. B. H.]

CHANGES IN THE MORPHOLOGY AND FUNCTION OF THE BONE MARROW AFTER SPLENECTOMY.

JOHNSTONE, ERNEST M. (*Archives of Surgery*, July, 1922) presents a profusely illustrated article on this subject and draws the following conclusions:

My conclusions regarding marrow changes after removal of the spleen are based on a series of experimental studies of twenty dogs, forty rabbits, and two goats during a period of approximately two years.

The new method of marrow study which I devised for this series of experiments consists of five essential features: (1) a rib marrow specimen removed before splenectomy is used as a control for a series of subsequent specimens removed at intervals after splenectomy. (2) Series of similar rib marrow specimens from normal nonsplenectomized dogs furnish an additional control for the experiments. (3) Rib marrow specimens removed at frequent intervals after splenectomy give a connected picture of marrow changes. (4) The observations on the marrow are correlated with parallel observations on the blood and on the general condition of the animal. (5) Ether anesthesia and cocaine anesthesia are used in separate series of experiments in order to test the influence of the anesthetic on the marrow.

Removal of the spleen of a normal animal is followed by definite hyperplasia and hypertrophy of the marrow. The most constant and the most important change in the marrow is an increased production of red blood cells which is clearly observable, on the average, within four weeks after splenectomy and

which gradually increases to the maximum about the end of the twelfth week. This maximum degree of activity persists for about twelve weeks and then gradually subsides. Increased production of the white blood cells is sometimes spectacular; it occurs almost immediately after splenectomy, but it is not only inconstant, but also temporary.

The reaction of the erythropoiesis in the bone marrow clearly is independent of any of the anesthetics used. The series of experiments is too small for conclusive findings with regard to the effect of the anesthetics on leukogenesis.

The marrow reaction which follows splenectomy probably is secondary and compensatory to the anemia which follows removal of the normal spleen, thus representing a physiologic response to a demand for more blood cells. It may have no direct relation to the absence of the spleen. The persistence of this marrow reaction, which far exceeds the duration of postsplenectomy anemia, may likewise be an expression of the law of regeneration in excess.

VALUE OF BLOOD PRESSURE IN ACUTE CEREBRAL COMPRESSION.

MALONE, J. Y. (*Annals of Surgery*, June, 1922) writes as follows:

Medullary compensation following increased intracranial pressure is a constant phenomenon experimentally when the anesthesia is not deep enough to block the corneal reflex or the reaction of the pupil to light, but is absent when the anesthesia is deep.

The depressor fibres in the vagus inhibit the rise of blood pressure following increased intracranial pressure.

Clinically, blood-pressure compensation following increased intracranial pressure is a valuable criterion of the degree of cerebral compression when the pupils react to light, but is of no service when they do not.

A sluggish or absent reaction of the pupils to light indicates a grave prognosis and no time should be lost in relieving the cerebral compression.

It has been an almost invariable rule, however, on the Neuro-surgical Service not to decompress a patient if the blood-pressure is falling or is below normal. This has been taken as evidence that the last stage of compression has been reached and that the medullary centres are exhausted and can no longer compensate.

[E. H. R.]

EXTRACRANIAL ANEURISM OF THE INTERNAL CAROTID.

WINSLOW, N. (*Annals of Surgery*, June, 1922) writes as follows:

Aneurism of the cervical portion of the internal carotid artery is not as infrequent as supposed.

Before incising a unilateral lump in the neighborhood of the tonsil, especially if of long standing, look, feel, listen.

Spontaneous cure may occur, but the usual termination in untreated cases is death from rupture into the fauces.

The operation of choice is occlusion of the internal carotid proximal to the sac. If this be impossible then ligation of the common carotid artery, together with a ligation of the external carotid, between its origin and first branch. If the external carotid be tied distal to a branch, that branch must likewise be occluded.

After ligation the prognosis is fair both as regards operative recovery and permanent cure.

Aneurism in other localities is by far more prevalent in the male than in the female; in the internal carotid it occurs in almost an equal ratio in the two

sexes, being slightly more prevalent in the male if all types are considered, but much more frequent in the female in the spontaneous variety.

[E. H. R.]

THE SERUM TREATMENT OF ANTHRAX SEPTICAEMIA.

SYMMERS, D. *Annals of Surgery*, June, 1922) writes as follows:

Every anthrax lesion of the skin or elsewhere should be tentatively regarded as attended by generalized infection until the result of the blood culture proves the contrary.

In no circumstances is it justifiable to tamper with the anthrax pustule—incision, excision, cauterization, or similar treatment is dangerous, and may be followed by anthrax septicaemia. The only permissible form of local treatment consists in the injection at the periphery of the pustule of broken doses of anti-anthrax serum at intervals of four to six hours, each injection not to exceed a total of ten or fifteen c. c. Failing this, it is better to cover the lesion with a bit of sterile gauze to collect the secretions, but otherwise to leave it absolutely alone.

The most dependable routine method in the treatment of the anthrax pustule is, first, to isolate it within a barrier of anti-anthrax serum subcutaneously injected every four hours; second, to inject intravenously, at once, a sterilizing dose of one hundred and fifty or two hundred c. c. of serum, and, third, to supplement this by the intravenous injection of forty c. c. every four or eight hours. If the blood culture is negative at the end of twenty-four hours, the intravenous use of serum may be discontinued, the local injections being kept up until the pustule is free from bacilli, or at least until involution forms occur in the stained films. In anthrax septicaemia, the liberal use of anti-anthrax serum intravenously, if commenced in time, is capable in many instances of sterilizing the blood with astonishing rapidity, and, in septicemic cases, the routine just outlined may be followed until the blood cultures are negative.

[E. H. R.]

ANOTHER CASE OF BULLET WOUND OF THE FEMORAL ARTERY AND VEIN SUCCESSFULLY TREATED BY LIGATION OF THE ARTERY AND VEIN AND EXTIRPATION OF THE INJURED SEGMENT.

LARQUE, G. P. *Annals of Surgery*, June, 1922) writes as follows:

When one studies the broad principles involved in the treatment of the immediate and remote effects of injuries of large blood-vessels and the results of isolated and collected cases treated in different ways throughout the world, one can scarcely escape the conviction that for arteriovenous lesions of the external iliac or femoral vessels the proper treatment consists of aseptic excision of the wound and lesion and all that this implies; in other words, ligation of the artery and vein above and below, and extirpation of the involved segment. The large number of cases of arteriovenous fistula on record and the monumental contributions of that great truth finder, W. S. Halstead, leave little room for doubt that this is the proper treatment for arteriovenous wounds of this character and location and for arteriovenous aneurism or fistula.

[E. H. R.]

SPONTANEOUS LATERAL VENTRAL HERNIA.

HOLTOWAY, J. K. *Annals of Surgery*, June, 1922). The author defines the lesion, reports a case with operation, and gives a brief historical sketch, speaks

of the etiology, and the pathological anatomy and diagnosis. He gives a chart showing the results in seventeen cases. This is an obscure condition and the article is timely in pointing out its rather rare occurrence.

[E. H. R.]

SPIRAL FRACTURE OF THE TIBIA AND FIBULA.

CALDWELL, JOHN A. *Annals of Surgery*, June, 1922) believes that the Parham band is an ideal method by which to hold these difficult fractures. He reports ten cases. His arguments are convincing.

[E. H. R.]

PERITONITIS AS A COMPLICATION OF PROSTATECTOMY.

VANDEN BERG, HENRY J., and BUTLER, W. J. (*Annals of Surgery*, June, 1922) call attention to the rather infrequent occurrence of peritonitis following the supra-pubic operation for prostatectomy, but also emphasize its possibility and report a case.

[E. H. R.]

SCIATIC HERNIA.

SUMMERS, J. E. *Annals of Surgery*, June, 1922) gives a very good historical though brief review of the literature on this subject and illustrates his article with some very excellent anatomical drawings and photographs of a patient operated on, and reports the operation in detail. The article is of considerable value.

[E. H. R.]

AN IMPROVED METHOD OF SKIN GRAFTING.

PARCE, A. D. (*Annals of Surgery*, June, 1922), after a considerable experience with war injuries, has devised a rather unique method of applying skin grafts. He uses a sterile dental composition as a mould, makes an exactly fitting outline and mould of the area to be grafted, with this pliable material. After it has hardened, he covers the under surface of his mould with an ordinary Tiersch graft, holding it in place by several catgut sutures over the top of the mould. The area to be grafted is properly prepared and the edges of the area slightly undermined so that the material with its flat graft fits snugly, a few interrupted catgut sutures hold the material in place, sufficient pressure is applied for 6 to 10 days to prevent the accumulation of any serum which would tend to raise the graft from its bed.

The article contains several very excellent illustrations of the technic and the results.

[E. H. R.]

FILIARIASIS IN PANAMA.

McFARLAND (*American Journal of Tropical Medicine*, Vol. No. 3, May, 1922) reports the finding of microfilaria in 31 out of 1124 persons examined. None of the individuals harboring the parasites showed any symptoms or lesions recognized as referable to its presence. About half of the cases were in hospital for other conditions, and the remainder were presumably healthy laborers.

The writer says that the ordinary methods of staining the organism proved unsatisfactory in his hands, but that a saturated alcoholic solution of methylene blue gave excellent results. He worked with thick smears laked in tap-water.

SUBSCRIPTION TERMS: \$6.00 per year in advance, postage paid for the United States, \$7.50 per year for all foreign countries belonging to the Postal Union.

Material for early publication should be received not later than noon on Saturday. Orders for reprints must be sent to the printer with galley proof of paper. Upon written request, authors will be furnished free one hundred eight-page reprints, without covers, or the equivalent in pages in articles of greater length.

The Journal does not hold itself responsible for statements made by any contributor.

Communications should be addressed to The Boston Medical and Surgical Journal, 126 Massachusetts Ave., Boston, Mass.

THE RELATION OF FOCAL INFECTIONS TO MENTAL DISEASE.

THE question as to the exact relationship between focal infections and mental disease is one that is attracting considerable attention and discussion at the present time. There are those who feel that focal infection is the long looked for explanation of dementia praecox and manic depressive insanity, and that proper therapy directed against this cause will produce a very high percentage of cures. Perhaps the most vigorous advocate of this view is Dr. Henry A. Cotton, Medical Director of the Trenton State Hospital, New Jersey. According to Cotton,¹ "Psychoses arise from a combination of many factors, some of which may be absent, but the most constant is an intracerebral, bio-chemical, cellular disturbance arising from circulating toxins, originating in chronic focal infections situated anywhere throughout the body and probably to some extent in disturbances of the endocrine system." The principal organisms which produce these focal infections are the streptococcus (both hemolytic and non-hemolytic types), the staphylococcus, and colon bacillus. The primary foci of infection are the teeth, tonsils, gastro-intestinal and genito-urinary tracts. The treatment consists in the operative removal of infected teeth, tonsils, and other organs, in the use of autogenous vaccines and

a serum immunized to streptococci and colon bacilli.

Under such a system of therapy, it is stated that, in the last three years, over one thousand patients of the so-called "incurable" group have been discharged and that the discharge rate for the "functional" group has been raised from thirty-seven per cent. to between sixty-five and seventy per cent.

It is unfortunate that but little work has been done to prove or disprove Cotton's results. We must confess with shame that almost none of our State hospitals has the equipment, the physicians or the money to undertake such a piece of work. Perhaps the publicity given the whole subject will result in an aroused public opinion which will demand and secure adequate facilities for our hospitals for mental diseases.

There have, however, been three pieces of work to which it might be well to call attention. The Report of the Research Committee financed by the Michigan State Dental Society² maintains that all previous work on bacterial cultures from teeth have necessarily given unreliable reports due to inevitable contamination. Using a perfected technique, it was found that thirty-three per cent. of pulpless teeth in cases of myocarditis, nephritis, arthritis or neuritis gave negative cultures. It was also held that if properly treated, a non-vital tooth may remain uninfected for years.

Kopeloff³ has made a very careful study of the gastric contents both as to chemical analysis and bacterial content. Briefly, he found that single determinations of gastric acidity by the Rehfuess fractional method are unreliable, that there was no correlation between degree of acidity and number or type of bacteria present, that the swallowed saliva markedly impaired the value of bacterial examinations and that aliquot fractions do not accurately represent the total gastric contents. He concludes that the Rehfuess method is not a valid procedure with which to establish the stomach as a focus of infection and an etiological factor in the functional psychoses.

Cheney⁴ carried through two series of cases, one group having all foci of infection removed and the other group having no attention paid to such foci. He was unable to show any marked difference in recovery rate between the two groups.

The relation of the focal infections to mental disease is still unknown. The reports of various workers are conflicting. Perhaps the situation can best be summed up by quoting from Adolph Meyer's foreword in Cotton's "The Defective, Delinquent and Insane." "If these lectures stimulate physicians and laymen to furnish means for extensive, well controlled trials, I shall feel that the somewhat extreme claims which go beyond what I personally believe to be my experience, may find their excuse in good

results. Let the best agencies come together and give the best talent, the best opportunities for work from all sides. Let criticism be constructive and not only restrictive."

THE SHEPPARD-TOWNER ACT.

THE Children's Bureau has approved the plans of thirty-six states for the administration of this law. Forty-two states have accepted the act. Although up to July 14 the Louisiana Legislature was still in session, no action had been taken in that state. The Louisiana Senate Committee on Health and Quarantine reported unfavorably on the bill to accept the Federal Act. New York and Rhode Island have taken the same attitude as Massachusetts.

H. M. Towner, one of the authors of the original bill, has rendered an opinion on the constitutionality of the act. This seems to be a reply to the opinion given by Attorney-General Allen. Judge Towner argues that the law is constitutional under Article I, Section 8, of the Federal Constitution, which gives to Congress the power "to lay and collect taxes, duties, imports and excises, to pay debts and provide for the common defense and general welfare of the United States." His reasoning is based on the preamble and on many classic works relating to the Constitution and the interpretations set forth by various speakers and writers in dealing with the provision embodied in the words, "general welfare." It is his opinion that these words justify an existence of the Public Health Service and he claims that if this part of the Constitution cannot be interpreted to make legal provision for the Sheppard-Towner Act, then some other national activities are operating without legal authority.

As types of legislation which may be construed as valuable precedents, he refers to the land grant college appropriations, the Smith-Lever Act of 1914 for instruction in agriculture, the Smith-Hughes Act of 1917 for vocational education, and the Federal grants for highway construction.

It would be futile for an unprofessional critic to attempt to make any logical argument relating to a constitutional question, but a layman may justly feel that in the presence of differences of opinion, expressed by recognized exponents of law, those states which have decided to wait for the opinion of the Supreme Court have adopted the same course.

There are in operation throughout this country at the present time certain customs which have been adopted for the purpose of meeting

the wishes of some people, about which there is the shadow of suspicion that, if the highest courts should be asked for opinions as to the legality of acts adopted by state legislatures authorizing these customs, some enacted laws may be found to be unconstitutional. It should be kept in mind that no law is really established until it has been contested and been passed upon by the Supreme Court. Massachusetts, through her Attorney-General, has assumed leadership in a movement which will determine the standing of the Sheppard-Towner Act. When the decision of the Supreme Court shall have been rendered the whole country will be under obligation to the Bay State. If constitutional, then the way is clear for those states which believe in the policy of Federal bounties to states to be applied under Federal approval, to unite with the government in carrying on state activities.

RESPONSIBILITY FOR THE ENFORCEMENT OF LAW.

IN the July 13, 1922, edition of the JOURNAL an article dealing with the history and psychology of quackery, by Robert W. Lovett, was published. It was a strong presentation of facts and a logical analysis of human weaknesses. The older men in the profession could give testimony confirmatory of the tendencies of many of the people to apply to the ignorant pretender for relief from physical ills. The men who have entered upon the practice of medicine since 1900 can hardly realize the earlier extent of these foolish customs, for the itinerant quack has almost universally gone to his reward, and the number of poorly equipped practitioners has steadily decreased. But even though conditions have improved in some respects we have new problems presented in the development of the evils which call for solution. In all the states efforts are being made to regulate the irregulars and protect the people from inadequate or improper service. These efforts are of two kinds, one designed to provide for better qualified physicians, and the other to inhibit or eliminate the pretender who blatantly advertises his methods as cure-alls.

Laws relating to the control of medical practice have been formulated to meet conditions as they appeared from time to time, and have been productive of good so far as they have been enforced and upheld, but in some instances have been found to be more or less obnoxious because occasionally, in their application, a well intentioned but poorly informed physician has unwittingly been annoyed by the exaction imposed.

It may be necessary to have at some convenient time a survey of the laws enacted by this State for the purpose of ascertaining which ones should be retained and which discarded, for even among intelligent and honorable men there are

differences of opinion. As examples, the law relating to the association of a registered physician with one not entitled to practice, and the status of the unregistered associate with the legally qualified doctor might be discussed. Also, the law relating to the practice of obstetrics. In illustration of the difficulties encountered under the example first mentioned—a practitioner recently sent a medical student to attend a case which he, the registered man, had not seen. The student failed to appreciate the gravity of the case and the family secured the services of another physician who found the patient suffering from a dangerous disease and sent the case into a hospital. Death supervened in a few hours. The circumstances were reported to the police. The doctor who sent the student was disciplined by the Board of Registration in Medicine and complaint against the student made to the prosecuting authorities. There appears to be some evidence tending to show that prominent and influential physicians have felt that the registered physician and the student should have been dealt with more leniently.

This same tendency to interfere in the application of the law has been shown in the testimony submitted by a physician in good standing when several midwives were being prosecuted by the State police. This physician testified, as an expert, that the practice of midwifery is not the practice of medicine, and on the strength of this medical opinion the judge found the defendants not guilty. In a subsequent trial before a jury the same physician repeated his testimony and, although it was shown in the evidence that one of the midwives had advertised as such for many years and at the time of the birth of a child had applied drops to its eyes, some of the jury were so impressed by the physician's opinion that a disagreement resulted.

These alleged facts seem to demand some action by the profession, for it is disconcerting for officers of the law to find that their efforts at enforcement do not meet the approval of physicians. Either these laws should be enforced or they should be stricken from the statutes. Unfortunately, the State cannot appeal from an adverse decision by a judge or a jury, and although the Supreme Court has upheld our medical laws in every instance when appeals have been carried thus far, serious obstacles seem to be encountered in the antagonism of our own members.

We are united in our opposition to the cults; should we not carry reforms within our own ranks so far as the laws may be made effective? Will the State Society act to either change the laws or to exert its influence for enforcement of them?

DENATURED ALCOHOL.

The Internal Revenue Commission has authorized the use of the following formula by visit-

ing nursing associations, public nursing associations, clinics and dispensaries which are of semi-public character and engaged in charitable work:

Ethyl alcohol, one hundred gallons, to which is added twenty-five fluid ounces of phenol U.S.P., four fluid ounces of oil of wintergreen or methyl salicylate U.S.P.

This is a reasonable concession, but alcoholic preparations are still unduly expensive. There should be some way provided by which the legitimate use of alcohol might be secured at true cost. Alcohol is not expensive to manufacture and the price is much more than should be required of hospitals and laboratories devoted to scientific operations which have no commercial purpose.

THE EXAMINATION OF FOOD HANDLERS.

ALTHOUGH the Department of Health of New York City has carried on some work relating to the health of food handlers, it is stated that less than ten per cent. of these people are examined for the purpose of ascertaining whether such persons are suitable ones to be distributing food. Of this small number examined less than one-fourth are examined by physicians employed by the health department. Even with this inadequate investigation seven typhoid carriers have been discovered in the past seven years, or on the average, one a year. If the proportions of typhoid carriers in the other more than 90 per cent. is approximately that found in the examined class, there would be about nine typhoid carriers handling food-stuffs. This may not seem a large number, but as possible foci of infection many cases might result from these sources.

NEWS ITEMS.

JOICHI TAKAMINE.—The death of this eminent chemist occurred in New York, July 22, 1922. Dr. Takamine was born in 1854, and had been living in Passaic, New Jersey, for several years. He is credited with the discovery of adrenalin in 1900, and takadiastase in 1894. His education was secured in Japan and Glasgow. He was chemist to the Japanese Department of Agriculture and Commerce when he achieved distinction. Most of the time since 1890 he had lived in this country and was deeply interested in promoting amicable relations between this country and Japan. He was a member of many scientific and social organizations.

THE PUBLIC HEALTH INSTITUTE OF CHICAGO FINANCES A COÖPERATIVE RESEARCH.—The Public Health Institute of Chicago has undertaken

to finance the cooperative research between the University of Wisconsin Medical School and the Chemical Department of Northwestern University, which in the past has been supported by appropriations from the United States Inter-departmental Social Hygiene Board. This research which has been devoted to attempts to improve the treatment of syphilis of the central nervous system has been directed by Dr. W. Lee Lewis and Dr. Frank C. Whitmore of Northwestern University, and Dr. A. S. Loewenhardt and Dr. W. F. Lorenz, of the University of Wisconsin. The Public Health Institute has appropriated \$21,600 to both universities for the coming year.

THE LAWRENCE MEMORIAL HOSPITAL.—By the bequests of Daniel W. Lawrence, Roswell B. Lawrence, and the gift of a site by Mrs. Carolyn R. Lawrence, Medford is to be provided with a modern hospital. The contracts have been awarded and the work has been begun. The design is by Charles B. Dunham with Stevens & Lee consulting architects. The general character of the building is of modified Georgian type. The dimensions are 148 by 125 feet, two stories, with a third story over a portion of the center for the operating department. The general scheme provides for such future additions as may be needed for a large city. In addition to the equipment for general medical and surgical services, there will be a maternity department with a children's ward. It is claimed that this is the first hospital in New England which is equipped with rubber tile and ceilings especially treated to absorb noises and insure silence. All the arrangements and equipment are of modern design and when completed this hospital will be a model to be studied.

FEDERAL SOCIAL HYGIENE BOARD.—The inter-departmental Social Hygiene Board has passed out of existence and a bill has been introduced in Congress authorizing the Department of Justice to take over the work formerly conducted by this board. Surgeon-General of the Army M. H. Ireland, Surgeon-General of United States Public Health Service Hugh S. Cummings, and others, recommended this change. It is felt that the Department of Justice, coöperating with State and local health officials, can deal with the questions pertaining to prostitution and venereal diseases.

MEETING OF THE BARNSTABLE DISTRICT MEDICAL SOCIETY. On August 4, 1922, this society will meet at the Barnstable County Infirmary at Pocomsett. This meeting is arranged especially for social as well as professional entertainment, and is called under the title of "Ladies' Day." All physicians, whether members of the society or not, are invited to attend with their wives.

WINTHROP COMMUNITY HOSPITAL.—Mention has been made in the public press of the closing of the Metcalf Hospital in Winthrop. The geographical location of Winthrop seems to demand a local hospital, for the transportation of emergency cases to metropolitan hospitals would entail inconvenience and suffering. The nearest accessible institution is the Chelsea Memorial Hospital, which is often taxed to its capacity. The inability of Dr. Metcalf to carry on his hospital because of impaired health has led prominent citizens and the physicians of Winthrop to inaugurate a campaign for funds by which hospital service can be maintained and extended. The only other place where medical service can be dispensed, aside from that provided by private physicians, is the Health Department Dispensary. An executive committee, consisting of Mr. G. Wallace Tibbetts (chairman), Dr. Frederick G. Dews, Messrs. Preston B. Churchill, Eugene P. Whittier, Charles R. Bemison, Albert S. Smith, William H. Gardner, A. W. Belcher, T. W. Berridge, J. S. Carr, Thos. Davidson, R. A. Lang, A. B. Reade and Israel Sisson have the matter in charge. Dr. Bernard W. Carey is acting in an advisory capacity in addition to the physicians of the city. The drive for funds has taken the form of a stock-selling campaign. About \$5,570.00 worth of stock (non-dividend paying) have been sold. There is a possible fund of \$20,000 subscribed under a previous drive conducted last spring. The plan is to purchase the Metcalf Hospital and enlarge it to thirty beds' capacity with all necessary equipment. This will be regarded as a temporary plant to be used until a more permanent hospital may be built with the expectation of converting it into money and applying the proceeds to the erection of a modern hospital whenever sufficient funds may be available.

WEEK'S DEATH RATE IN BOSTON.—During the week ending July 22, the number of deaths reported was 174 against 166 last year, with a rate of 11.87. There were 29 deaths under one year of age against 28 last year. The number of cases of principal reportable diseases were: diphtheria, 36; scarlet-fever, 20; measles, 58; whooping-cough, 34; typhoid-fever, 3; tuberculosis, 42. Included in the above were the following cases of non-residents: diphtheria, 1; scarlet-fever, 3; whooping-cough, 1; typhoid-fever, 2; tuberculosis, 3. Total deaths from these diseases were: diphtheria, 1; measles, 2; tuberculosis, 13. Included in the above were the following cases of non-residents: tuberculosis, 2.

DR. GEORGE MONROE PALMER of Lynn died suddenly at Floating Bridge Pond in that city, July 21, 1922, at the age of fifty-nine.

He was born in Rochester, N. H., in 1863, graduated from Harvard Medical School in the

class of 1892, joined the Massachusetts Medical Society in the same year and settled in practice in Boston. His interest was in internal medicine and in chemistry. Following 1908 he lived successively in Cambridge, Watertown and Belmont, moving to Lynn in 1919. Later he was employed in the chemical laboratories at the State House. He is survived by a widow and a son.

Miscellany.

LEGISLATIVE MATTER.

MENTAL HYGIENE.

THIS act passed in the later sessions of the Legislature is supplementary to the letter of Dr. L. Vernon Briggs in the issue of July 27:

CHAP. 519.

AN ACT ESTABLISHING THE DIVISION OF MENTAL HYGIENE IN THE DEPARTMENT OF MENTAL DISEASES.

Be it enacted, etc., as follows:

SECTION 1. Chapter nineteen of the General Laws is hereby amended by inserting after section four the following new section:—Section 4A. There shall be in the department a division of mental hygiene, under the supervision of a director. The commissioner, with the approval of the governor and council, may employ such expert assistance to serve in said division as may be necessary.

SECTION 2. Chapter one hundred and twenty-three of the General Laws is hereby amended by inserting after section three the following new section:—Section 3A. The department shall take cognizance of all matters affecting the mental health of the citizens of the commonwealth, and shall make investigations and inquiries relative to all causes and conditions that tend to jeopardize said health, and the causes of mental disease, feeble-mindedness and epilepsy, and the effects of employments, conditions and circumstances on mental health, including the effect thereon of the use of drugs, liquors and stimulants. It shall collect and disseminate such information relating thereto as it considers proper for diffusion among the people, and shall define what physical ailments, habits and conditions surrounding employment are to be deemed dangerous to mental health.

SECTION 3. Said chapter one hundred and twenty-three is hereby further amended by inserting after section thirteen the following new section:—Section 13A. Such of the powers and duties conferred or imposed upon the department, relating to the cause and prevention of mental disease, feeble-mindedness, epilepsy and other conditions of abnormal mentality, as the commissioner may determine may be exer-

cised and performed by the division of mental hygiene. In addition to said powers and duties, said division shall institute inquiries and investigations for the purpose of ascertaining the causes of mental disease, including epilepsy and feeble-mindedness, with a view to its prevention. It may also establish, foster and develop out-patient clinics. (Approved June 8, 1922.)

POST-OPERATIVE COMPLICATIONS OF THE RESPIRATORY TRACT.

DR. H. RYERSON DECKER, F.A.C.S., of Pittsburgh, Pa., says in *Current Research in Anesthesia and Analgesia* "that complications of the respiratory tract develop after operation with greater frequency and more serious consequences than most surgeons and anaesthetists appreciate. No clinics and no clinicians are immune, especially if they make careful observations and keep accurate records. Collected figures that are reliable, such as given in Table 1, show that on the average one case in every forty-five operated upon develop a respiratory tract lesion and that one case in every two hundred dies from this complication.

TABLE 1.

	Operations.	Morbidity.	Mortality.	Morbidity Per Cent.	Mortality Per Cent.	Mortality of Morbidity Per Cent.
Cutler & Morton, Mass. Gen'l.	3,490	65	1.8	33	.94	50.7
Armstrong, Montreal Gen'l.	2,500	55	2.2	32	1.28	58.1
Mayo Clinic	16,317	220	1.32	15	.11	9.6
Von Lichtenberg	23,073	440	1.9	11	0.7	20
Cutler & Hunt, Peter Brigham	1,562	55	3.52	11	0.7	20
Decker, Pittsburgh, 1920	5,976	69	1.2	29	0.5	42
Decker, Pittsburgh, 1921	2,125	16	0.7	6	0.3	37.5

"Last year I reviewed a series of 5,976 cases operated upon consecutively in the surgical services at St. Francis Hospital and my own at Presbyterian Hospital, Pittsburgh, in which series the morbidity was 1.2 per cent., and mortality 0.5 per cent., both comparatively low figures, as seen by Table 1. However, one should make due allowance for statistics. In our series we excluded minor cases which had no anaesthetic or remained in the hospital less than two days, cases of primary surgical respiratory tract disease, *e.g.*, suppurative pleurisy, in which respiratory tract complications are to be expected, cystoscopic examinations, and finally nose and throat cases, *e.g.*, tonsillectomies for which the patients remain in the hospital so short a time, that records of the post-operative course are not available. Nor in our report did we take cognizance of the milder respiratory tract complications, such as coryza, pharyngitis, and tonsillitis, inasmuch as they involved no serious consequence to the patient, and, furthermore, were incompletely recorded.

"In the last sixteen months, from January 1,

1920, to May, 1921, we have extended our observations, and now report a review of 2,125 cases from the same sources as in our previous study (the surgical services of R. T. Miller, Mercy Hospital, R. R. Huggins, B. Z. Cashman, W. O. Sherman, and E. W. Meredith at St. Francis Hospital, and my own at the Presbyterian), and with an even lower morbidity and mortality of 0.7 per cent. and .03 per cent. respectively, as seen by Table 1.

The morbidity by disease is shown in

TABLE 2.

	1920	1921
Lobar Pneumonia	45	8
Broncho-Pneumonia	7	6
Bronchitis	7	2
Pleurisy:		
Dry	7	1
Sero-fibrinous	2	..
Empyema	1	..
Pulmonary Embolism	2	..
Pulmonary Abscess	0	1
	71	18
No. of Patients.....	69	16

"The series shows the usual preponderance of pneumonia, this time nearly equally distributed between the lobar and lobular types. This corresponds more nearly to the findings in other clinics although Cutler, in 1600 cases at the Peter Bent Brigham Hospital this last year, has found only one case which he has called lobar pneumonia.

"It is beyond the limits of this paper to enter into a full discussion of the clinical course of the post-operative respiratory tract complications, so we shall present only a brief summary of some of the important features as we have observed them, in order that we may more fully consider what to us is of more practical import, their etiology and treatment.

"Pneumonia is by far the most frequent and serious complication, in our series, being responsible for 75 per cent. of complications and 90 per cent. of the mortality. Autopsy reports are scarce, but those published show that there may be every known type of pathology, including lobar, lobular (broncho), embolic (infarction), gangrenous, hypostatic, and, lastly, a type important and frequent, which corresponds to a type of non-surgical pneumonia called by the French School, *maladie de Woillez*, and indeed resembles closely, as we have seen it, the gross appearance of *influenza pneumonia*."

The writer then proceeds to give the clinical and pathological features of each complication.

This is an important summary of the dangers of anaesthesia and to the occasional etherizer is of especial value in so far as it may lead to recognition of well known dangers which may not have been observed by a recent graduate who under force of circumstance may be called upon to administer anaesthetics. Since these

accidents occur in the cases cared for by trained men the facts should be made known to friends of patients.

APPROPRIATIONS FOR PUBLIC HEALTH WORK.

Among the appropriations made during this session of Congress the following items appear:

Navy Appropriations.—Care of lepers, Navy Station, Island of Guam, \$18,000; for necessities, Medical Department, \$2,400,000; contingencies, Bureau of Medicine and Surgery, \$435,000; bringing remains of sailors and marines from France, \$65,000; care of naval hospital patients, \$85,000; complete construction naval hospital, San Diego, Calif., \$500,000.

Army Appropriations.—Water and sewers at military posts, \$2,000,000; Letterman Hospital, California, \$55,000; claims officers, nurses and enlisted men for pay and allowances during World War, \$500,000; construction and repair of hospitals, \$529,360; maintenance of quarters for hospital stewards, \$10,000; medical and hospital department of army, \$1,000,000; hospital care, Canal Zone garrisons, \$40,000; Army Medical Museum, \$7,500; library, surgeon-general's office, \$12,000; office of surgeon-general, \$223,280; artificial limbs, trusses, etc., \$36,750.

Department of State Appropriations.—Annual share of United States in maintenance of International Sanitary Bureau, \$11,323.16; annual quota of United States in support of the International Office of Public Health, \$3,860; annual contribution for support of Somerset Hospital at Cape Town, Africa, \$50.

Department of Justice Appropriations.—Enforcement of national prohibition act, \$250,000; hospital supplies, medicines at various federal prisons, about \$15,000.

Treasury Department Appropriations.—For expenses to enforce national prohibition and narcotic acts, \$9,250,000; pay and other expenses, Public Health Service, \$2,196,530; maintenance of Hygienic Laboratory, \$45,000; medical examination of aliens, \$5,627,394; quarantine service, \$739,000; prevention of epidemics, \$400,000; field investigation of diseases, \$300,000; Interstate Quarantine Service, \$25,000; rural sanitation, \$50,000; biologic products and viruses, toxins, etc., \$50,000; maintenance of Venereal Disease Division, \$400,000, of which sum \$225,000 shall be allotted to states for co-operative work; repair of Public Health Service hospitals; Otten, N. C., No. 60, \$100,000; Perryville, Md., No. 42, \$150,000; West Roxbury, Mass., No. 44, \$50,000; Palo Alto, Calif., No. 24, \$50,000.

Independent Bureaus Appropriations.—Medical and Hospital Services, \$64,658,680; Vocational Rehabilitation, \$146,409,188.80.

Interior Department Appropriations.—Sup-

pressing liquor traffic among Indians, \$30,000; relieving and preventing disease among Indians, \$370,000; investigation of school hygiene, etc., \$50,000; medical relief in Alaska for Eskimos, \$90,000; investigations of safety of miners, \$378,000; operation and purchase of mine rescue cars, \$285,000; operation of St. Elizabeth's Hospital for Insane \$1,000,000, repair to buildings \$100,000, erection of additional buildings, \$128,500; Columbia Institution for Deaf, \$95,000; Freedmen's Hospital, \$118,555.

Labor Department Appropriations.—Children's Bureau, \$106,040; investigation of child welfare, \$120,000; Maternity and Infancy Act, \$1,240,000.

Agricultural Department Appropriations.—Tuberculosis in animals, \$2,877,600; inspection of meat, \$981,180; prevention of sale of adulterated foods, \$671,401; enforcement of Insecticide Act, \$156,510; dehydration of foods, \$20,500.

Deficiencies.—Continuing construction of Galinger Municipal Hospital, District of Columbia, \$150,000; United States Veterans Bureau, additional for vocational rehabilitation, \$40,000,000; medical and hospital services, \$25,000,000; investigation of women in industry, \$1,800; Public Health Service, Interstate Quarantine Service, \$466; medical and hospital service for disabled war veterans, \$87,776.81; medical, surgical and hospital services, \$130,000; Quarantine Service, \$389,000; prevention of epidemics (emergency), \$1,000; support of National Home of Disabled Volunteer Soldiers, \$514,700; medical charities, District of Columbia, \$23,170.45; support of indigent insane at St. Elizabeth's Hospital, \$148,000; Employees Compensation Commission, \$600,000; United States Veterans Bureau, vocational rehabilitation \$73,714,182, medical and hospital services, \$20,287,930; administration of Warehouse Act, \$9,015; care of insane in territory of Alaska, \$8,800; Children's Bureau for maternity and infancy welfare, \$490,000, to be apportioned among the various states; alterations and repairs to Fort Mackenzie, Wyoming, hospital, \$100,000; for additional land to Walter Reed General Hospital, \$94,703.44; United States Veterans Bureau, authorizes transfer of appropriations from Veterans Bureau to United States Public Health Service; United States Public Health Service authorized to use appropriations already made for operation of immigration hospital at Ellis Island; adjustment of Walter Reed General Hospital land purchases, \$44,709.22.

AMERICAN RELIEF ADMINISTRATION.

A CONSTANT stream of serums and vaccines to fight the epidemic diseases which are raging in Russia, particularly in the famine sections,

and to those centers of population to which the famine refugees have fled, is flowing from the great laboratories of Paris to Moscow and thence into each plague-stricken town and village. Every courier of the American Relief Administration arriving in Russia brings fresh consignments of the life-saving drugs. The Medical Division of the A. R. A. is bending every effort to carry out its prophylactic program, which involves among other items the inoculation of every child receiving its rations and of every adult who receives the American gift of corn, and to all others who may apply for it.

The inoculation is proceeding rapidly throughout the 16 districts where the American medical supervisors are coöperating closely with all the health organizations of the Soviet hospitals and all of the health agencies of the Soviet government.

Every American Relief Administration feeding station, every school where feeding is carried on, every orphanage that draws American Relief Administration rations is a clinic for the administration of the preventive remedies which will help to stop the spread of the contagion.

Not only serums and vaccines are distributed, but the hypodermic syringes, the needles and the sterilizing materials needed for their administration. The activities of the Medical Division, which was at first only a small part of the American Relief Administration's program, are rapidly becoming one of its outstanding features. The scale upon which the inoculation against disease is being carried on is a stupendous one.

Vaccination against smallpox has been a general practice for years in many countries, but this is the first time in history that an attempt has been made to protect upon so extensive a scale the inhabitants of a country against cholera, typhoid, para-typhoid "a", para-typhoid "b", and smallpox at one and the same time.

Each patient with his first inoculation of the tetra vaccine which gives immunity to the first four diseases named above, also receives the ordinary smallpox vaccination, unless he can show evidence of a previous vaccination. Eight million cubic centimetres of the tetra vaccine have already been ordered and 3,500,000 doses of smallpox vaccine.

In addition to the tetra vaccine already mentioned, 300,000 cubic centimetres of triple vaccine and a million of cholera vaccine have been provided, not to speak of the anti-toxins which run into huge figures. For example, of the diphtheria anti-toxin 91,000,000 units is the provision. Six million units of tetanus anti-toxin, 200,000 of antimeningococcal serum and a like quantity of polyvalent anti-dysenteric are other items on the list.

RESUME OF COMMUNICABLE DISEASES, JUNE, 1922.

GENERAL PREVALENCE.

THERE were 6,846 cases of communicable diseases reported for this month as against 8,793 for May.

Chicken-pox.—There were 325 cases reported for this month.

Diphtheria decreased from 558 cases for May to 459 cases for June.

Dog-bite requiring anti-rabic treatment was reported in 29 instances. This is a larger number than was ever before reported.

Encephalitis lethargica was reported in 5 instances.

Epidemic cerebrospinal meningitis was reported in 13 instances.

German measles decreased from 96 cases for May to 52 cases for June.

Gonorrhea and Syphilis.—There were 381 cases of gonorrhea and 126 cases of syphilis reported.

Influenza was reported in about the usual numbers. There were 11 cases for June, 1922, and 12 cases for June, 1921.

Measles has begun its annual decline. There were 3,198 cases reported for this month and 4,159 for last month.

Mumps decreased from 514 cases for May to 375 for this month.

Pneumonia, Lobar.—There were 139 cases reported for this month.

Scarlet fever decreased from 755 cases for last month to 470 for this month.

Tuberculosis, Pulmonary.—There were 614 cases reported for this month.

Tuberculosis, other forms, was reported in 130 instances. There were 105 cases reported for last month. In both months the incidence was unusually high.

Typhoid Fever.—There were 41 cases reported for the month.

Whooping cough decreased from 415 cases for May to 359 for this month.

RARE DISEASES.

Anterior poliomyelitis was reported from Lawrence, 1; Lowell, 1; Somerville, 2; total, 4.

Dog-bite requiring anti-rabic treatment was reported from Brookline, 3; Cambridge, 1; Holyoke, 2; Lowell, 17; Newton, 1; Plymouth, 1; Swampscott, 2; Winthrop, 2; total, 29.

Encephalitis lethargica was reported from Boston, 3; Cambridge, 1; Taunton, 1; total, 5.

Epidemic cerebrospinal meningitis was reported from Boston, 1; Concord, 1; Hingham, 1; Lawrence, 1; Lowell, 2; Lynn, 1; Northampton, 1; Peabody, 1; Wrentham, 1; total, 13.

Habermia was reported from Boston, 3; Everett, 1; Holyoke, 1; total, 5.

Septic sore throat was reported from Amherst, 1; Boston, 1; Fall River, 1; Somerville, 2; total, 5.

Smallpox was reported from Milford, 1.

Trachoma was reported from Boston, 4; Cambridge, 1; Lynn, 1; Medway, 1; New Bedford, 1; Somerville, 1; total, 9.

Trichinosis was reported from Holyoke, 1.

CHILD LABOR.

A SENSE of local responsibility for the welfare of the children is what is needed to abolish child labor, declared Herbert Hoover before the National Conference of Social Work in Providence, June 27. Failing in this, an amendment to the Federal Constitution must be sought as the only other alternative to overcome what he considers "a blight that in its measure is more deplorable than war." Forward looking states have passed statutes which fully protect the child in its minority, but there is still a minority of states which are "still in the Middle Ages in their attitude toward childhood." The sense of local responsibility is the only saving grace in this matter, and nothing can be more disheartening than the impulse given to centralization under Federal control by the continuous failure of local government in a matter affecting the nation as a whole so vitally as does the question of child labor. An industry that cannot exist without cheap child labor has no right to exist. A nation that continuously exploits its children is foreordained to fail.—*The Nation's Health*.

CHICAGO'S RAT PROBLEM.

THE business men of Chicago have secured the services of an expert in rat extermination work in order to reduce the danger and financial loss incident to the presence of rats.

The health commissioner has endorsed this movement and promised cooperation. Federal authorities claim that there are as many rats as human beings in this country.

Correspondence.

DIGITALIS IN CARDIAC DISEASE.

NEW YORK, July 19, 1922.

Mr. Editor:

In reading the able and instructive article in your issue of July 13 of Dr. Henry A. Christian, I find the following on page 53: "I know of no cardiac case in which it is necessary to substitute any other drug for digitalis." This statement is far too sweeping and to my mind will occasion, not infrequently, loss of life, if followed, and also be the cause of protracted disease which might be treated successfully with at least one other drug, and that is strophanthus. I have saved lives with tincture of strophanthus in hypodermic tablet form, used sublingually, when I am confident digitalis would have been useless. I have helped restore to strength weak, irregular, fluttering hearts, when digitalis made symptoms worse. For detailed information about "sublingual medication," I refer to my article in *Medical Record*, Dec. 29, 1917.

PAPERS AND DISCUSSIONS OF THE SECTION OF HOSPITAL ADMINISTRATION.

AT ITS MEETING AT THE HARVARD MEDICAL SCHOOL, BOSTON, JUNE 13, 1922.

THE USE OF PATHOLOGICAL MATERIAL IN SMALL HOSPITALS.

By JOHN F. KENNEY, M.D., PAWTUCKET, R. I.

It would be more interesting and far more instructive if this subject were discussed within the four walls of my complete little laboratory in the Memorial Hospital at Pawtucket, R. I. Since we cannot treat it in a concrete way, I will endeavor to give you a fair idea of what we have accomplished in this particular hospital along pathological lines.

Let us take up the subject under three heads: first, the laboratory proper; second, the director and laboratory workers; third, the work that can be done in a small laboratory. To start a laboratory requires only a small amount of money. It is surprising to see what one thousand dollars will do towards equipping a laboratory. All you need at the outset is a room with good lighting and proper plumbing. In my present laboratory we started without even these essentials but made our improvements as we went along. My advice is to start on a small scale and equip yourself as you find the need for it.

In selecting your room, if you have a choice of position make it as close to the operating room as possible, as such a position is very convenient in doing section work. In addition to the laboratory proper, a small animal house in a remote part of the hospital grounds or even on the roof is essential and a morgue for autopsies is, of course, very necessary, while light and ventilation are supremely important factors. While in the army I found from actual experience that a laboratory can be started and in working order in a surprisingly short time. In two instances I was sent to a camp or post with orders to start a laboratory. Upon arriving, in each instance the commander led me to a certain part of the hospital building and pointing to an empty room, informed me that that particular room was to be the laboratory. It was then entirely my own problem. In a short time the room was completely transformed, so that we were able to take care of this branch of the work which was of the utmost importance.

No matter how large or small the hospital, its laboratory director should be a physician. No technician should be given complete charge of a hospital laboratory, for, although a pathologist may, in many cases, be perfectly competent to discover that tests are necessary and to carry them out successfully, yet the training of a physician is essential for diagnosis and for advice as to treatment. Consequently, a physician as laboratory director is, in my opinion, a *sine qua non*. The director should perform all au-

topies. He should himself interpret all results and reports before they leave the laboratory, except in an emergency. For instance: The technician may report a 2+ positive cholestere in a patient who had just been under treatment but, if she reported the same in a case without any clinical symptoms, she would not be in a position to request further investigation and discussion with the doctor in charge, as she, in her position, is not required to know all the stages of syphilis and its peculiarities. In other words, she can do things mechanically and make reports of what she finds, but what a staff needs is a medical man to co-operate and advise. For example, in a case suspected of malaria or typhoid, if an increased white count were found, the doctor pathologist, because of his medical training, would know at once that malaria must be eliminated as a possibility, and would suggest other means and tests to arrive at a diagnosis in the incomplected case. This is only one of the numerous cases where the co-operation of a physician would be beneficial.

Remember, I am talking entirely of the smaller hospitals where it will be quite possible to obtain the services of a physician for part time work in the laboratory. Under this arrangement he may spend some time each day in the laboratory to give instructions, make reports, etc. In case he is needed, he will be available and is at all times a consultant. I know of no better way for a physician to start in practice than to ally himself with one of these positions. In his own practice he is much more efficient, especially if he has the pathological training; and above all he has confidence in himself because of this superior training. Nowadays, many of the hospitals are giving internships of one or two years in the laboratory. I know a number of men who settled in different sections of New England after a training of this kind and who have positions where they are able to make their own tests. These men have built up a private practice much greater than the men who were trained in clinical work alone. Many men in practice have not as yet availed themselves of the advantages and the advances made in laboratory aids to diagnosis. The World War was an important thing to these men as in every camp of any size the government furnished laboratories in charge of competent men. Because of the importance of this work, the hospital should pay the director the best salary possible according to its size. The average should be from one to two thousand dollars a year. Some days the physician may be obliged to spend several hours in the laboratory and other days he may be needed only minutes; nevertheless, he is always on call and ready for emergencies and is, therefore, entitled to a reasonable salary.

The technician is always a problem, as some are well trained and others have only a moderate training. However, any intelligent girl with some bacteriological sense can be taught labor-

atory work, and a year's course in theory is an excellent start, for she can be trained later by the director in the branches in which she is not already proficient. Many colleges give special courses in this line and have excellent results. However, I have discovered that nurses make especially fine technicians on account of their familiarity with the hospital routine and I have, therefore, advised that laboratory work in a general way, be included in every nurse's training. Having secured a good technician, pay her well. Otherwise, your smaller hospitals will be continually training girls who will leave as soon as they are able to command a higher salary in a larger hospital.

The work that can be done in a small laboratory is extensive and I believe of the greatest importance. To begin with, the laboratory checks up the operating room and wards on all sterile goods, materials, etc. Wassermann reactions should be carried out as a routine on all patients admitted wherever practicable. Many obscure cases of syphilis that would otherwise be overlooked until after operation are discovered in this way. One case in particular of non-union of fracture made a good recovery after a plus finding and anti-syphilitic treatment. It is not difficult to have your own sheep and ambceptor from your own rabbits. Make your own complement from guinea-pigs, for these animals do not require much care and add very little expense to your laboratory. Guinea-pig inoculations are used also in T. B. cases or in renal diseases. Some of the other routine work done in the laboratory are blood-typing for transfusions, blood urea and blood sugar determinations and tests for cavity fluids, renal functions, smears, stomach contents, stools, blood cultures, spinal fluids, and Widal's. Let me now show you the vital connection between the laboratory and the hospital proper. All new cases in the children's ward should be isolated until a report is sent back that the throat cultures and vaginal smears are negative. All typhoid cases should have routine stool examinations and should not be discharged until negative. A cheek should also be made on the milk supply and in this way the hospital is protected from an impure supply. Frozen sections should always be available for the surgeon, but notice in advance should be given the pathologist so that he can be on hand at the time of the operation. It is unnecessary to take up in detail all the phases of the work that can be done in any laboratory, no matter how small. In my opinion, it is as necessary to the hospital as is the operating room.

In regard to autopsies, I believe that everyone connected with the hospital, from the superintendent down, should be interested in doing his share in obtaining them. As we all know from experience, people are loath to sign permits for autopsies, but they are so essential that all should bend their energies toward obtaining a

permit when the case is in any way remarkable. As many nurses and physicians as possible should attend each autopsy as it is on the autopsy table that we learn what we might have done. The completion of the autopsy report and records is important, but it should not rest with that, for each case should be taken to the staff meeting and there discussed.

The maintenance of a laboratory is not such a big financial problem. It should not be considered a producing department any more than a public ward should be. A charge to each patient admitted of from one to four dollars for a ward patient and a minimum of five dollars for private patients, with an extra charge for other tests done, has been carried out successfully by us. In this way a revenue that helps to support the laboratory but does not completely cover all expenses is obtained. We have seventy beds in our hospital and our last year's report shows seven thousand, seven hundred and seventy tests. We have the advantage perhaps of having a majority of our staff connected with the larger hospitals in a bordering city and naturally you would expect them to be up in the modern methods of diagnosis. But, in any city or town where a hospital is located the same advantages and methods are available. The entire outlay for a laboratory, together with the expenses for running it, costs less than any other branch or hospital department, and I venture to say that no branch is more important. Any hospital of any size should have and can have a laboratory. Educate the men on the staff to use it and better results will be obtained in treating the patients and it will make more proficient medical men. Every test made in the larger hospitals can be made in a small hospital. Many hospitals have no laboratory facilities at all. They run a large overhead expense, build substantial buildings, have beautifully kept grounds, and no laboratory. I have in mind one hospital with a complete staff, in a city of about forty thousand. I don't believe they have even a microscope. They depend on a state laboratory, which is some distance away, to take care of their work. In these progressive times this seems to me an injustice to the people of a community. Let us hope that in the future every hospital, old and new, large and small, will be equipped with a laboratory.

DISCUSSION.

DR. CYRUS C. STUBBS, Boston: I think Dr. Kenney has mentioned one very important part of the work of the laboratory of the small hospital, and that is autopsies.

I have no general statistics available, but all the small hospitals that I know anything about either have a very low autopsy record, or make no attempts at all to obtain them. Just why this condition exists I don't know, but it seems to me that they must either fail to appreciate the value of autopsies, or they are not using proper methods in obtaining them.

In the 1920 report of the Chicago Academy of Medicine, some 27 or 30 hospitals in Chicago were investigated and it was found that the autopsy record in these hospitals varied from 48 per cent. down to

none at all in nine hospitals. The highest, I believe, was the Presbyterian Hospital of that city. Of the nine hospitals with no autopsies, the majority were small hospitals. Only a few weeks ago, in talking with a representative of a hospital in the Middle West about autopsies, he remarked that he made an attempt to get autopsies only in interesting cases. I think really the most valuable autopsies are those cases which may appear very commonplace from the clinical standpoint, and therefore the thing to do is to attempt to get autopsies in every instance. Of course it is impossible to get 100 per cent., but I believe just the routine asking of the relatives of every patient who dies would give us 25 or 30 per cent. at least.

Now there are plenty of illustrations of how very commonplace cases may prove to be of great value when autopsy is done. Just within the past few weeks at the Peter Bent Brigham Hospital we have had some striking ones. A man was in the hospital five days and died at the end of that time with a diagnosis of acute nephritis, and there was very good evidence to substantiate it. An autopsy was made and the man was found to have typhoid fever with an intestinal perforation. Another case on the surgical side was that of a patient who had an acute appendicitis, was operated on, and died on the operating table. The assumption was, though there was no evidence particularly to support it, that the patient died of too much ether. At autopsy a pituitary tumor was found. Those are just cases that have happened recently.

Every physician ought to appreciate the value of autopsy. Needless to say, the staff that does not get the advantage of correlating their clinical studies with autopsy findings misses a great deal. The pathologist's part adds just as much to the care of patients as the other laboratory work, such as X-rays, etc.

As to the method of getting autopsies, I should like to tell you of our experience at the Peter Bent Brigham Hospital. Our record on the medical service for the four years previous to 1920 averaged 42 per cent. The first few months of 1920 the autopsy record commenced to fall and got down to almost 25 per cent. At that time a campaign was started to obtain more. We used simple means; in the first place instructing each house officer to ask for permission for autopsy in every single death. Failing to obtain permission, he was to call the resident physician. The record of every death was made to show who was responsible for trying to get the autopsy, whether or not he could get it, and if not, why. Each house officer during his senior term kept a record of the number of autopsies he was able to obtain, and his percentage of autopsies was figured up and given publicity. Since that time we have had 66 per cent. autopsies. For the six months of 1922 the percentage on the medical side has been 76 per cent. One man who is just finishing his senior house officer's term now has an autopsy record of 31 out of 38 deaths, or 84 per cent. This shows that a little enthusiasm and energy put into the work really counts. A small hospital can do it just as well as a large, if the effort is made systematically.

This is a very proper section in which to discuss this matter. I am glad it came up. I believe the superintendent and the administrative staff of the hospitals are largely responsible for success or failure in obtaining autopsies. If they are opposed to autopsies you will not get any; if they are indifferent you will get a few; if they are interested and enthusiastic, you will get many.

DR. P. W. GOLDSBURY, Deerfield: How far are physicians informed, so that they can benefit by any public autopsies or findings of this sort?

DR. KENNEY (answering Dr. Goldsbury's question): I might as well discuss autopsies here now. We went down to eight per cent. in our hospital, and we have, as I said, a 70-bed hospital. It was simply that some

of the men were indifferent. There were only two internes, and of course a surgeon cannot be on the job all the time. It might happen that you could not find the interne on the medical service and the surgical interne did not bother about it. So finally we got the trustees to get into the game. Sharp letters were sent to all the men on the staff, and it is surprising that since January first of last year our autopsies are up pretty close to 50 per cent. The superintendent is also supposed to look after them if she possibly can.

I recall a case that was sent in by a man who happened to be the local medical examiner. The superintendent tried to get an autopsy, but found that the people absolutely refused to have anything to do with anyone connected with the hospital. It was not impressed upon them that something might be found that would be of value to the medical profession in general, so finally the local physician was sent for, appealed to by the surgeon, made a call before they took the body away from the hospital, and finally came back with a signed permit.

Notice of the autopsies are posted on the bulletin board so that the men on the staff will know about them when they come. We cannot publish it in time to get all the local physicians, but most of them are interested in medical matters, and when the man who sent in the case is notified, he is told to bring in any others that he may desire.

DR. W. H. MERRILL, Lawrence: The Lawrence General Hospital, a hospital with 125 beds, has an arrangement with the laboratory of Tufts College Medical School for the examination of pathological material. I have not been told about the expense, but it is so much for a certain number of examinations. The hospital has a resident technician, and the consulting pathologist does not have time to devote to such details as seem necessary.

DR. H. P. STEVENS, Cambridge: I might say a word in regard to the Cambridge Hospital. They have a contract with the Harvard Medical School, Department of Pathology. It has proven very satisfactory. Of course the Cambridge Hospital is near enough so that material can be sent by messenger, and we get reports back very promptly. The same contract provides us with a pathologist for autopsies, and the hospital has never had a resident pathologist. I don't know what it costs, but it is not expensive, and for a hospital within easy access it is a very good arrangement.

Of course where we want immediate frozen sections, that is outside of the contract, and we have to send for a pathologist for the occasion, and we make use of such service to some extent. There is a similar contract for the more elaborate laboratory tests. The hospital makes no effort to do anything but ordinary routine laboratory work, and all other tests are done under a contract with the school.

DR. H. G. STETSON, Greenfield: That is the one thing that was in my mind when I saw the title of this paper. We have a small hospital, but no arrangement whatever for careful microscopic examination of any organs removed, and the only arrangement is a personal arrangement which I have with Dr. Wright. It is some years since I made this arrangement, and it has continued to be satisfactory. It came out of a desire or a wish that we could utilize more of the pathological material removed not only at autopsies but at operations. We are not able to have a pathologist any more than any other small hospital unless it has an enormous endowment. But in any hospital some arrangement could be made with a laboratory whereby this service could be given.

DR. P. H. LEAVITT, Brockton: In Brockton our situation has been largely the same as that described by the three gentlemen who just spoke. We have a small private hospital of forty beds and no resident

pathologist. We have a laboratory, a medical man to look after the ordinary laboratory work, having a very competent bacteriologist at City Hall do the Wassermanns, but the examination of the fresh specimens has been our bugbear. We now, however, have a satisfactory personal arrangement with Dr. Mallory whereby the specimens are examined.

My purpose in rising was to ask whether the diagnosis of fresh specimens by a man doing part laboratory and part general practice was in all cases as accurate as could be desired. We found, trying it out a few years ago, that when diagnosis was made by the part-time pathologist and then later checked up by the consulting pathologist, the results did not always agree. Everybody would, I am sure, be very much interested in finding a part-time pathologist who could absolutely be depended upon. Are there many of them about?

DR. KENNEY (answering question of Dr. Leavitt): Answering that question, of course that is true about everything you would take up. It depends upon the man you get.

With regard to the diagnosis, if a man is interested in pathological work, he won't have to put in a lot of time. The majority of men are interested in some one specialty. For instance, we have through Rhode Island a number of men, a medical man, a surgeon, perhaps a nose and throat man, who will employ a technician together and establish a laboratory, employing perhaps a full-time man if they are in possession of their own laboratory. They get satisfactory service in this way.

In regard to the part-time man, every now and then you will find some man starting out in practice who would like a location. In your city of Brockton you might find a man who would want to locate there, perhaps a younger man who had had some laboratory training. In the Rhode Island Hospital there is a pathologist in charge and for two years he has been doing nothing but pathological work, but several laboratories have the younger men who want part-time work. The pathologist at the Springfield Hospital is a man with training under Dr. Mallory.

About the frozen section work; if a man is interested at all he is going to try to keep it up, and begin in frozen section work as well as the other branches.

With regard to sending specimens to the Harvard Medical School and other hospitals, arrangements made that way are very good and you accomplish a great deal more than if you had a technician and no supervision. There are so many things you can do, however, if you have your own laboratory and pathologist. For instance, a man wants a checking up of blood urea and blood sugar. He has the goods right there, calls in, leaves the order, and the next day the case is taken care of and you don't have to send out. Of course it takes more time to send to another laboratory, and perhaps it is a case of waiting for operation, so if you have to send to a State laboratory, for instance, it takes quite a good deal of time if you have to wait.

In our hospital perhaps 70 per cent. of the cases are surgical, and we are getting a routine of perhaps 300 specimens sent to the laboratory. We have a routine of sending everything, just as in the autopsy work, for sometimes the most unimportant cases apparently turn out to be important. All this takes a man who must be interested in that work.

It is a good idea to try to get a man who can give full time at first, and then part time, gradually getting away from it and letting some other man get into it. But of course with frozen sections a man has to keep up with his work.

DR. J. B. HOWLAND, Boston: There is no doubt that in the last few years there has been a decided change in the attitude of hospitals towards getting post-mortems. I think most of them have felt that the Hebrews have been against granting autopsies be-

cause of religious scruples. I was pleased to see, however, that the Trustees of one of the Jewish hospitals in New York have just passed a resolution favoring the making of autopsies. There is also an interesting article in the "*Modern Hospital*," May, 1922, by Dr. Bluestone, Assistant Director of the Mt. Sinai Hospital in New York, describing methods whereby that institution gets a large percentage of autopsies from their patients, who are largely Jewish.

I was hoping that some one would discuss the subject of the procedure of handling pathological material in hospitals that have no pathologist. I am confident that there is often an arrangement between small hospitals in Massachusetts whereby pathological material is sent to the Harvard Medical School to be examined.

I believe that by writing to the pathological department of the Harvard Medical School, Superintendents of small hospitals can make arrangements to have pathological specimens sent there for diagnosis.

I would like to ask Dr. Kenney whether he thinks that year or two that the man stays in the pathological work is sufficient so that one can rely upon his diagnoses?

DR. KENNEY (answering Dr. Howland's question and closing): That would depend where he received his training. If he had had a lot of section work in a large hospital he would have training enough to be relied upon.

WHAT MEDICAL AND SURGICAL STATISTICS SHOULD BE PUBLISHED IN THE ANNUAL HOSPITAL REPORT?

By DAVID CHEEVER, M.D., BOSTON.

THAT the question of hospital statistics has long been agitated is attested by the fact that, in 1860, Florence Nightingale¹ proposed a plan for uniform hospital statistics and a nomenclature of diseases, to the Fourth International Statistical Congress, in London.

An outstanding tendency in modern medicine is that having to do with the evaluation of existing methods and practices and the more or less wide adoption of standard practices throughout the country. The hospital standardization movement, the effort to standardize the practice of surgery by the American College of Surgeons, to standardize medical schools by the Rockefeller Foundation, to standardize end-results of hospital treatment, to standardize the nomenclature of diseases, are familiar examples. Indeed, so pronounced is the tendency that the individualist might feel anxiety at the prospect of a prescribed level of respectable attainment, and the loss of the occasional flash of brilliancy attained by untrammelled individualism.

It is natural that hospital librarians, executives and staff, resting from their labors at the close of the "open season" on the compilation of reports, should wonder whether their labor has been worth while and whether changes in the system should not be made.

What information should the annual report aim to give and make into a permanent record? The hospital might be regarded as an organization which receives certain raw materials and

aims to turn out a certain finished product, and it would certainly appear reasonable that a report of the year's work should include a statement of the raw materials and of the results accomplished. But as a proper tribute to the founders and benefactors of the institution, it is thought essential that a brief account of its founding and history shall be given, together with a list of benefactions. A list of those who have served it in the past helps to awaken the interest of the public; the list of those in its present employ naturally follows. The treasurer feels it to be his duty to account for his stewardship by a list of the invested funds, and a statement of income and expenditures; the superintendent or administrator presents the details, financial and otherwise, of his affairs. The pressing needs of the institution are set forth to excite the generosity of its friends. The vital statistics of the patients admitted are justly important from a social economic point of view, so tables of age, sex, nativity, color, social condition, occupation, etc., are laboriously presented. Finally, the account of the function for which the hospital exists, namely, the cure of disease, is given in the form of statistical tables which indicate the number of individuals of each sex afflicted with each variety of disease, whether the application of surgical methods was made or not, and the result as expressed in the general terms "well," "relieved," "not relieved," or "dead."

Thus was evolved the complex, costly and little read hospital report of today, consisting of hundreds of pages of laboriously prepared data. What is the circulation of these volumes and what, in general, their final disposition? Who reads them? Local inquiry in Boston does not encourage an impression that they are regarded as important. Doubtless each hospital has a complete file of its own reports, but no local hospital, with one exception, pretends to keep files of its sister institutions, yet one would suppose that precisely to hospital administrators would appeal to greatest degree the records of the others. At the Massachusetts General Hospital it is the aim to have complete files of the reports of all New England hospitals, and of as many as possible of the major hospitals of the country. At present there are complete files there of ten or twelve major hospitals in recent years, and this is the most complete collection in Boston. At the Boston Medical Library there is no pretense at filing and cataloging the reports. In the libraries of the Massachusetts General Hospital, the Boston City Hospital and the Boston Medical Library it was reported that there is no call for these reports; the occasional inquirer seeking them usually for a name or an address. At the Boston Public Library, the library of Harvard University and the Boston Athenaeum they are not preserved. The library of the Harvard Medical School is glad to receive these reports and catalogues them, but the files

are far from complete. It is here, apparently, that most use is made of them, for students, especially during their fourth year, frequently consult them in order to ascertain the amount and general character of the work done at the hospital, with a view to making up their minds where they had better apply for interne positions. The library of the Surgeon General's Office, in Washington, as would be expected, "maintains a very complete file of all this material, and it is estimated that the annual reports of about 800 hospitals are on file in the Document Division. While the demand for these reports is not as large as for current medical literature, it is sufficient more than to justify the attempt to make these files complete."²

The volumes are sent to the managers and trustees, to the members of the visiting staff, to the former house-officers, to friends and benefactors, past and prospective, to members of the city government if the institution be a municipal one. It is safe to say that not one recipient in a hundred does more than to glance idly at the pages. Perhaps the banker looks at the investments, the executive manager reads details of administration and the per capita per day cost, the philanthropist may read of the annual deficit and of the needs of the institution, and the physician glances at the medical and surgical statistics and perhaps examines with real interest the mortality rate of some particular disease or surgical operation.

The elaborateness of reports of large hospitals in recent years is scarcely realized except by those who compile or study them. The report of the Massachusetts General Hospital for 1916 was a handsomely printed volume of 567 pages. The list of occupations of patients occupied 14 closely printed pages and included about 575 occupations of men, and half as many again of women. With all the enthusiasm in the world for the study of the relation between occupation and disease, or for the solution of sociological problems by investigating the occupations of those who resort for treatment, it is difficult to attach much significance to the fact that one major, United States Army, and one social reformer were treated in 1916. Are we to infer that officers in the United States Army who are above and below the rank of major are less liable to disease because they do not appear on the list? In the butchering trade there may be a delicate professional distinction between ham skimmers and ham boners, but we are at a loss to explain why two of the former and one of the latter should have fallen ill. Was the one Hebrew teacher one of the chosen people, or merely a teacher of Hebrew, or both? Did the 14 deep-sea fishermen suffer from mal-de-mer, and if so what should afflict the 16 plain ordinary fishermen? I confess to real curiosity as to the ailment of the lonely lumber in an undertaker's shop. Did he have melancholia or the *douloureux*, or did he dislocate his mandible

from inordinate mirth? To be serious, this elaborate list is useless as showing any relationship between sickness and occupation, and its economic importance would be covered by classifying patients into the wage earners, salaried persons, capitalists, etc.

The medical and surgical data published in most reports consist of statistical tables showing the number of patients suffering from each disease, the sex, and the condition on discharge expressed by such terms as "well," "relieved," "not relieved," and "dead." There is further a table showing the operations performed, and the result couched in similar terms. Some hospitals, notably the Massachusetts General and the Peter Bent Brigham, have added brief abstracts of the operative fatal cases. Of just what use are these statistics? They give a good idea of the incidence of disease in a locality for a given year, as far as concerns the classes of diseases admitted to a particular hospital, but this usually does not include the epidemic and contagious diseases which chiefly interest the epidemiologist and health officer. They afford information as to the general medical and surgical flavor of the hospital; for instance, one hospital in a certain city will be distinguished for its wealth of traumatic surgery, which is brought to it by the police, or which comes to it on account of its location in congested industrial centres, while a neighboring hospital will receive but little accident work but will be the resort of many patients with pathological lesions such as tumors, parasitic diseases, etc. Many such instances readily come to mind. It is my experience that medical students consult these statistics in order to form an opinion as to where they may expect to find the kind of interne service which they desire.

Of true scientific value, it must be confessed, there is little or none. The data concerning each patient is so utterly inadequate that the work of hospitals, or the hospital work of communities cannot be compared. There is but beginning to be uniformity of nomenclature in diagnosis, and the terms used to designate the results of treatment are so vague (except the word "dead!") and involve so much of the personal equation, that just comparisons are impossible. Even the abstracts of surgical fatalities, in which the writer was a believer at first, seem of limited value. They serve, indeed, to recall to the surgeon the circumstances of his failure and to impress upon him anew errors and pitfalls which might have been avoided, but to other readers they seem like apologies, too brief to be of scientific value.

It seems, therefore, that the medical and surgical statistics do not in any sense constitute an adequate presentation of the work of the hospital as a contribution to existing medical knowledge. It might seem strange to the layman that such contributions as the Johns Hopkins Hospital Reports, the former Medical and Surgical

Reports of the Boston City Hospital, and similar volumes from various hospitals of New York, Philadelphia, and London are not the rule, rather than the exception. In former years when medical journals were few, the members of the staff of a hospital found the annual report the best, perhaps the only available vehicle for making known their work, but the subdivision of the general field of medicine into specialties, each of which has its special journals, each having a far wider circulation than could a hospital report, has resulted widely in the discontinuance of the latter and the resort by members of hospital staffs to the journals as means of publishing their work. The average hospital cannot compete with the medical journal, either in the matter of circulation or financial support. Doubtless this is to be for various reasons regretted, but it must be accepted as a fact.

But there is another side to the shield.

No student in the history of medicine, indeed no one who brings a trace of the philosophical viewpoint to the practice of his profession, can fail to find much of interest in a study of these dull statistical medical and surgical reports over a period of years. Turn, for instance, to the annual reports of the Boston City Hospital, which included these statistics from its foundation until they were omitted in 1916-1917. In 1865, there were performed 185 surgical operations, among which were but two laparotomies, both for ovarian cyst, and both patients died! Chiefly were the surgeons concerned with amputations, 44 in number, ligations, reduction of dislocations, operations for fistula in ano, for haemorrhoids, for the "radical cure" of hydrocele by injection of irritating chemicals or by inserting a seton; it is not until 1889, twenty-four years later, that the radical excision of the hydrocele sac appears in the list. Under the heading of "Results," it is specified whether healing was primary or secondary. Truly, surgery as we know it today was practically non-existent. There were years after this, even up to 1883, when not a single laparotomy was performed! "Peritonitis" occurs as a diagnosis early among the medical diseases, but it is not until 1882 that "typhilitis" and "peri-typhilitis" appear, but from then on these diagnoses are frequent, and it appears that peritonitis was usually fatal and peri-typhilitis was not. The suspicion is justified that these were almost all cases of acute appendicitis, and those localized in the right iliac fossa got well, while those developing into general peritonitis died. In 1887, following the demonstration of the disease by Fitz, in 1886, the diagnosis of appendicitis occurs for the first time, and from then on the diagnosis of typhilitis and peri-typhilitis soon disappear, and peritonitis ceases to be a medical diagnosis. An epitome of the history of the operative treatment of hernia is furnished by the appearance in succeeding reports of Wood's operation, Hea-

ton's operation, MacEwen's, McBurney's, and finally in 1893, Bassini's operation. The tragedy of diphtheria before anti-toxin is revealed by the 78 tracheotomies in 1884 for laryngeal diphtheria, with 56 deaths, with the substitution of O'Dwyer's intubation in succeeding years, so that in 1888 we find intubation used in 100 cases with 78 deaths, and tracheotomy used only in 17 desperate cases, all fatal, where the lesser procedure failed. We can afford to smile now at the diagnosis of a single case of chronic ulcer of the stomach on the medical service in 1883, and the 52 cases of dyspepsia, gastrodynia, pyrosis and gastro-duodenitis. Such interesting side lights on medical history may be multiplied a hundred fold.

Let it be admitted, then, that the medical and surgical statistics of the annual hospital report have but little true scientific value, but afford a rough survey of the incidence of non-fatal diseases in the community at a given time, of the results of treatment grouped in certain broad classes, and give opportunity for the comparison of these facts in different years and epochs in different communities. Exactly these data are not to be obtained, so far as I know, from any other source. In addition, the statistics afford some basis, inadequate it is true, for comparison of the kind of work done in different hospitals, and are much used by medical students and doubtless others, in determining in what institutions they will seek to continue their training. The real question at issue is, Do these advantages justify the time, labor and money put into the compilation of the reports? In this connection it will be admitted probably that the essentials of these statistical tables should be prepared annually and kept on file in the hospital record room in some easily available form, as is now done at the Massachusetts General Hospital, even if they are not published. The additional labor to prepare them for the printer would be slight, so that the issue boils down to whether or not the statistical tables are worth the cost of printing and publishing them. The writer, who, by the way, does not have the duty of trying to make both ends meet in hospital administration, believes that they are worth the cost, and that reports would be the less significant without them. But the reports should be condensed, shortened, and made uniform as to nomenclature and method of compilation, throughout a community, or better, throughout the country. The tables of medical and surgical diseases should be combined, since the only difference between them (with few exceptions) is the therapeutic method employed. Minor sub-varieties of disease should be omitted and broader grouping attempted. The results of treatment should be grouped solely as "relieved," "not relieved" and "dead," for the term "well" is usually quite inapplicable. The table of surgical operations is really no more essential than one of serum or hydrotherapeutic

treatments for the medical service, yet it constitutes such a striking method and excites so much interest that it had better remain. It is not easy to combine it with other tables, but its complexity can be greatly reduced. For inconsequential verbosity it is only necessary to refer to the enumeration of the 57 different varieties of tinkering which are carried out on the female genitalia. The writer believes also that the synopsis of operative fatalities is not worth while.

While not strictly germane to the title of this paper, the writer wishes to point out other possibilities for the report. The suggestion has been made that major hospitals throughout the country, under the direction of a central organization, should take up annually some subject of special interest and report the experiences of each hospital in the appointed subject for the preceding year or series of years. Such a subject might be, for instance, the results of treatment of fracture of the neck of the femur. Thus annually would be available an enormous amount of data on the actual results of diverse methods of treatment of the same condition in the hands of the members of hospital staffs throughout the country, which could not fail to be enlightening. However, this would be a return to the principle of scientific hospital reports, which, with noteworthy exceptions, have been given up for reasons before noted. The same survey of hospital work in limited fields could be secured by agreement among members in existing scientific societies to investigate and report on the same subject during a given year, the result appearing as communications in existing journals.

The writer feels that the annual hospital report should contain a carefully prepared study of the professional work of the hospital during the preceding year, written by members of the staff, preferably a surgeon and a physician who, having a philosophical bent of mind, could give an account of the influences dominating the treatment of disease during that time, the introduction of new methods, and the discarding of old. Think of what interest would attach to such running contemporaneous comment on the introduction of the principles of antiseptics and asepsis, the carbolic spray, ligatures, methods of wound treatment, rubber gloves, etc. One looks in vain in the old reports for such comment or information. New methods and practices creep in slowly and become a part of the every-day routine, and their existence can scarcely be inferred from the existing reports. We can scarcely believe it, yet it is certain that what we are doing today will be as historically interesting to our successors forty years hence as is the story of the "Listerism" of the early eighties to us now.

Let each agent in the work of the hospital, trustee, treasurer, administrator, and staff give an account of his stewardship in the annual report, but let it be condensed, simplified, clar-

fied, and let the purpose be to render it a document of semi-scientific and especially of historical value for the information of the world with regard to the work we are doing today.

DISCUSSION.

DR. J. B. HOWLAND, Boston: I think there has been very considerable evidence in the last ten years among hospital trustees and superintendents that they were wavering about what should be published in the hospital reports. Besides cutting down costs, I think there are other reasons, and doubt has crept in as to whether elaborate reports were worth while. They are costly to print and it is costly to keep up the tables in the record room. Hospitals that formerly published reports of hundreds of pages are now getting out brief pamphlets.

I think there must be among those present some with decided ideas as to what hospital reports should consist of. We should like to hear from you.

DR. W. P. BOWERS, Clinton: I haven't any very definite suggestions, anything more than an endeavor to express appreciation of the recommendations which have been made. I think it has been found very generally that interpretation of hospital reports has been a rather difficult task when one wanted to get definite information, so that if the reports can be made more concise, more definite, and I refer especially to the professional part of the report, I think they would be of tremendous value.

It seems to me that we can safely leave the financial features to the people who manage the hospital, to the superintendent and the trustees, but the scientific report, it seems to me, may be made very much more concise, very much clearer, and therefore better available for comparative purposes.

DR. H. G. STETSON, Greenfield: With reference to this subject, there were several years when we did not publish any report, largely from lack of funds. A hospital report costs from \$75 to \$150, and for many years the hospital could not afford it. There came a time when the trustees felt that they should have a report, and I was unfortunately the one who was picked to make up that report.

Our hospital is, like many hospitals, an open hospital, and any physician of ethical standing in the community has a right to bring patients in and take care of them. That year and the following year I went through the report of diagnoses given, and I prepared a list of diseases, and the number, as Dr. Cheever has said, the condition at discharge, etc. But as I went over it, the more I saw the less convinced I became of its actual value. When a baby a week old dies of chronic nephritis; or when a patient is admitted with some disease that is considered more or less chronic, like nephritis or cancer, and is discharged in three days as cured, there is something wrong.

Some of the diagnoses were unquestionably valuable, but I felt that there was a great deal of question whether statistics like that were of value or worth the printing. Furthermore, in hospital reports only a few hospitals follow any definite nomenclature. A few have the International, a few the Bellevue, and a few more the form that is used in the Massachusetts General Hospital, and others you could not classify according to any method. If you want to classify disease in different hospitals you have got to go ahead and re-classify the whole thing yourself.

One other thing that we should be more careful

about and have some definite plan to follow, is the report of hospital maintenance. There are many hospital reports in which you look in vain to see what the maintenance cost is, how much it costs per patient, where the money has gone, etc. This item is particularly valuable in the case of those who are interested in hospital expenditures, and in most hospital reports you will fail to see anything to tie to. One hospital keeps books one way, another in another way, and there is no way to compare expenses of maintenance in one hospital with those in other hospitals. The same is true of incomes; some call income one thing and some another.

The report of the Massachusetts Charitable Organizations in the form in which they submit it at present, comes nearer to being of value in giving out actual maintenance figures, but even in that there are sometimes inaccuracies.

I think there should be some definite system for small hospitals to follow so that they can compare their maintenance and upkeep with one another, to see whether they are keeping within the reasonable bounds.

DR. W. H. MERRILL, Lawrence: It may be a bit of encouragement to Dr. Cheever and others to hear the statement of one hospital which has made a decided advance in accurateness and completeness of reports.

The nomenclature used is that which the Massachusetts General Hospital has adopted, more reliable figures are presented, and the financial reports of this hospital are also accurately kept. There seems to be no difficulty in obtaining the figures of costs.

DR. H. A. CHRISTIAN, Boston: One criticism that can be made of all hospital reports is that they are deadly dull. No one feels any great amount of enthusiasm about reading them. They are dull not because interesting things have not happened, but they are dull because the incidents of the year are incompletely or poorly presented.

Dr. Cheever has referred to the failure to find in hospital reports any account of introduction of new methods and development of these methods, and so on. It seems to me that is a fair example of one of the defects of many hospital reports. Perhaps some of you are accustomed to read "Science" and if so, you will know that for the last two or three months there has been running in "Science" a series of letters stimulated by some one's making a severe criticism of the scientists of this country and their inability to present their work and discoveries in an entertaining way to the public. That writer went so far as to say that it was largely due to the misconception of the scientists that literature was not science, and a literary presentation of a subject was belittling the subject from the standpoint of science, because sentences must be crude and involved and more or less unintelligent. Perhaps a good deal of that would apply to medical men in connection with their hospital reports.

It seems to me that the statistical part of the report is quite worth while, but that it should not be carried to extreme by undue repetition, not very useful tables, etc. I think a discussion could arrive at the elimination of some of this, and the simplification of other parts, and a lengthening and greater detail in still others. The main thing, it seems to me, in looking over a report, is the running comment that gives you some idea of what it is all about, and what the hospital is doing, presented in a way that is intelligible not only to the medical man but to the non-medical man who may have an interest in the hospital, and presented in a way that, even though not entertaining, yet is a fair chronicle of what has happened in the hospital.

There are one or two hospital reports that stand out as being of interest and worth while. Dr. G. Alder Blumer of the Butler Hospital of Providence puts out a report that is well written, entertaining

and gives an account that is worth while reading, even though my interest in it was extremely minor. It was so well written that I enjoyed it for that reason. He describes well what is going on, and nearly every year there is some suggestion of very distinct interest and value in that report. This year I regret to hear his swan song as active superintendent.

If we can eliminate the deadly dullness of our hospital reports it will help to increase the income from people who have been interested in the hospital, and as a result make contributions or leave bequests in their wills. They must have their interest aroused by something that has been brought to their attention in the hospital reports.

Another thing that it is perfectly proper to put in a hospital report is a discussion of the defects of the organization or administration of that institution from the point of view of improving it, and from the point of view of letting others find out the failures as well as the successes and things which you approve of. The things which you dislike in your own job ought to be brought to the attention of the trustees, the superintendent, and so on. I think there is entirely too little criticism of one's self in most of the hospital reports describing hospital organization and hospital work.

DR. L. E. PARETINS, Boston: I have been interested in hospital reports since 1916, when I read the complete file of reports of several Boston hospitals. My interest was chiefly historical at that time. The Massachusetts Charitable Eye and Ear Infirmary has no separate history, but the facts of the founding, organization, etc., can be obtained from its annual reports. This is one real value of reports, but I believe that historical data might be given in some better manner, rather than in the present haphazard method. In reading any report I like to know to whom it is addressed. It makes a great deal of difference to anyone who writes if he has in mind the prospective readers, also, the writer should have a clear conception of why the report is written. Hospital Annual Reports are usually addressed to the trustees, who, though an important audience, constitute a very small part of the community. Would it not be a good thing for the writers of reports to consider a wider horizon and make a readable report that the community or average person could read with interest? The report should "sell itself" to the reader. Hospital administrators have not always kept this point of view in mind.

MRS. GRACE L. MYERS, Boston: As Librarian I have handled for many years the annual medical and surgical statistics of the Massachusetts General Hospital, and in these years have seen many improvements. At first this sort of thing used to appear, all in the same report: renal modis, floating kidney, movable kidney, nephropiosis. Of course, during my first year, when I was unfamiliar with medical nomenclature, they were all reported, much to my later mortification. No one should ever make up medical and surgical reports until after a long term of handling clinical records, so that such synonyms as I have mentioned can be recognized.

The war brought about a new condition of things at the Massachusetts General Hospital, which at first seemed difficult to meet. Expenses had to be reduced, and my own force of clerks was cut down just half. We were keeping up the clinical catalogues and the annual report, but work had to be minimized, and I find that in these two or three years we have been able to see a considerable improvement in methods. The war was not altogether an unmitigated evil. Whereas we formerly devoted one card to each patient, we now catalogue eight patients on the same card, which is an economy of space and time; and our statistics, which once required three months of steady work to prepare for publication, are now kept

on cards made up week by week and are not published, but kept on file. We have one card for each diagnosis, and this card shows the number of patients, male and female, with morbidity. A card on any diagnosis for a given year may be selected and statistics for that year obtained. The cards are filed in drawers, year by year, and comparisons may easily be made. There are at present six years reported in this way, and by pulling out three drawers, the statistics for the whole six years can be compared at a glance. It is a matter of only a few moments to collect figures upon any given diagnosis. Many doctors who have come to our hospital to look into our methods have expressed themselves as very well pleased with this plan, and in fact have said it was the best they had ever seen.

One good suggestion made by Dr. Cheever is that some subject of special interest for study should be agreed upon by the different hospitals in a community and the results printed in respective annual reports. This was discussed at a recent meeting of the Record Librarians, who agreed upon the excellence of the scheme, and the interest that would undoubtedly ensue.

DR. N. W. CAXON, Boston: What Dr. Cheever has said is in accordance with my own ideas, namely that the ordinary hospital report is altogether too long and there is much that should be left out. The essentials that he has named are sound and should appear in each report. There is no need of my naming them over again.

The only way of ever accomplishing anything is to standardize it and have each hospital report along the same lines. That must be qualified immediately by saying that a small hospital should not report along the same lines as the large general hospital or special hospital. The general form should be the same for all hospitals, but details must vary widely according to the type of hospital making the report. You have got to sub-divide it further, and this must be accomplished by being taken up by one central body like the hospital association or the American Medical Association, and worked out from the center of a central organization.

THE PLACE OF THE FULL-TIME AND PART-TIME PHYSICIAN IN THE MODERN HOSPITAL.

By ROGER I. LEE, M.D., CAMBRIDGE, MASS.

THE prodigious advances in medicine have inevitably created many new conditions, and many new problems. The future promises to show as great or even greater advances. Therefore, even if the new conditions of today are met and the new problems of today are solved, there will still be the necessity of change in the future. I doubt if anyone would be willing to recommend any plan as an entirely satisfactory solution even for the present, and it is reasonably certain that any plan which might be satisfactory today will not meet the conditions which will exist in several decades. Nevertheless, it ought to be helpful to face the situation as it exists today, and to attempt to guide some of the necessary changes into paths that not only seem usable for the present but also promising for the future.

The early conception of hospitals in this country, and I am speaking now perhaps more particularly concerning the Massachusetts General Hospital, with which I have the good fortune to

be connected, was that the hospital was an asylum for the needy sick. Persons with comfortable homes were expected to be taken care of at home as a matter of course. The leading practitioners of the locality gladly devoted a portion of their day to attendance on the sick poor at the hospital. It must be remembered that these were the days before Florence Nightingale demonstrated the value of the trained nurse. Operations were few and dangerous. The emetic and the purge wrought their havoc without preference for home or hospital. Likewise there was no advantage in comfort or convenience in being bled at a hospital. Then in rapid succession came a large number of events which entirely overturned the practice of medicine. Anaesthesia was discovered, and the surgeon was able to delve deeply in the secrets of the human anatomy upon a non-resisting and non-suffering patient. With the discoveries in bacteriology, surgical operation lost most of its dangers, but demanded an exact and special technique. Medical diagnosis and even medical treatment began to utilize cumbersome apparatus and elaborate procedures. Nursing became a recognized profession. Great laboratories grew up in connection with hospitals. We find the hospitals no longer as asylums for the sick poor, but as the amphitheatre of the best efforts of the master minds in all branches of medicine. Today the well-to-do demand the same advantages of the well equipped hospital which the poor possessed undisputed in the early period of transition. To meet these changing conditions there has been a very rapid increase in the number of hospitals. The medical profession and the laity have met in a common demand for more hospitals. The hospitals, although under the widest possible variety of auspices, have, generally speaking, many problems in common. More or less irrespective of the financial status of the patients, most hospitals conceive their functions as the care of the sick, research, and teaching. There is some confusion concerning the teaching function of a hospital. Every hospital does teaching, even in the restricted sense of medical teaching. Some of that teaching may be the formal instruction of undergraduate medical students, or it may be the informal teaching of visiting doctors, of internes, or of the staff.

With the development of hospitals there has been a considerable readjustment in medical practice. The complexities of medical practice rather naturally led to specialization which has gone to great length in medicine, particularly in the larger communities. We find that the professors of anatomy, of physiology, of chemistry, and in general of all the so-called fundamental sciences, are no longer practicing physicians, but are devoting their entire time to teaching and research. We can discern a similar tendency in the teaching of other professions, for example in law, and in engineering.

In the hospitals, we find that a number of physicians have been giving full time to the hospital in their specialties. The medical superintendent of the hospital, in a large hospital, not infrequently devotes his entire time to hospital affairs and does not carry on private practice. A decade or so ago, the hospital pathologist was in many instances still attempting to do general practice. Nowadays he is often on a salary and his activities are perhaps confined to hospital work and teaching. The rapid growth of the x-ray laboratory has shown a very similar trend. At first men worked with the x-ray, and did general practice. At a later period the men confined their attention exclusively to the x-ray, partly in the hospital, partly in private practice, and now we see a very definite trend toward the utilization of the full time of a considerable proportion of the professional personnel of the x-ray department in the hospital. In the twenty-odd years since Roentgenology was discovered, we cannot, of course, find a complete unanimity of action on the part of all workers in the x-ray, but I think that the trend must be obvious to all. Perhaps of wider acceptance but of the same general significance is the payment of salaries for professional services by the hospitals. The salaries are for the most part for part-time service but it is, nevertheless, a long step away from the old idea of gratuitous attendance on the sick poor in the hospitals.

It was inevitable that this same tendency for paid full-time work should develop in what we still elect to call the clinical branches, namely, the actual care of the sick patient. In many ways the full-time hospital physician and surgeon seem to be the almost inevitable and logical outgrowth of the present situation. I interpret full-time rather liberally, meaning that the hospital (often with an affiliated medical school) is the full-time physician's main interest and main source of professional income, and that he does not maintain a regular private office for private patients. By part time I mean that the hospital is only a part of the interest of such a physician and that another considerable part of the interest, perhaps usually the main interest, and the chief source of his income, is elsewhere; as a rule, of course, in private practice. Relatively only a very few part-time physicians receive a salary for their hospital work.

Even if it be granted that the instruction of medical students is better carried on by full-time clinical professors and a full-time teaching staff, it does not necessarily follow that our teaching hospitals (teaching in the sense of instructing undergraduate medical students) ought to be manned entirely or even controlled by full-time physicians, nor that the non-teaching hospitals (non-teaching in the same sense) ought to adopt the full-time plan, even if in the Mayo clinic such a solution has been complac-

ently accepted as meeting the obvious requirements of a somewhat unique situation.

The proposal of the full-time basis by no means has met with complete approval. It must be granted at once, I think, that a hospital with a full-time staff is more easily and perhaps more efficiently administered. Furthermore, a smaller staff also makes for ease and efficiency of administration. Again, in those hospitals in which there are working both full-time and part-time professional men, it has usually happened, when the requisite allowances for personality are made, that the full-time men have inevitably and naturally acquired the greater influence in the hospital. Nevertheless, the problem ought not to be solved on the basis of any of these advantages. The advantage of possible development of greater opportunities for scientific investigation, which certainly accrue to the hospital employing the full-time plan, will not, furthermore, of necessity be of decisive value. In that connection it must be recognized from the history of medicine that material advantages and scientific productiveness are by no means always closely parallel.

The disadvantages of the full-time plan are essentially that such a plan does not meet the needs of the community in a large way. Even when one grants that the teaching of medical students and of medical graduates may be more effectively done, and even if one grants, merely for the sake of argument, but which is certainly debatable, that the patients in such a hospital are as well or better cared for than under any other plan, there still remains the outstanding fact that under the full-time plan the hospital does not tend to maintain close contact with the community. The influence of a hospital under the full-time plan while very great as a demonstration institution would, nevertheless, probably be very much less in the community than a hospital with a much larger part-time staff. Despite the large hospital facilities at present, the overwhelming majority of the population do not become hospital patients except under special circumstances. This majority has now and is likely to have for some time its own physicians. For the common good of laity and physicians it is desirable that the scientific leadership and stimulus of the hospital should be brought to this majority of the community in every way feasible.

There is always, it seems to me, in the case of a part-time visiting physician or surgeon, a very fair exchange between the doctor and the hospital. The hospital offers the doctor a much needed opportunity to develop himself in the science and practice of medicine. At first he has to meet the criticisms of his elders and always he has to meet the criticisms of his internes. In partial payment the part-time doctor contributes to the hospital a wide variety of experience gained from private practice, some of which will be reflected in the actual care of the pa-

tients, and all of which should benefit the staff, the internes, the medical students, both undergraduate and graduate. Furthermore, a probably more important contribution in the contribution in terms of good will and appreciation of the community which may at times take a very substantial financial form. Partly due to the early traditions of the profession and partly due to the prodigious changes in medicine, the medical profession and all its appurtenances, such as medical schools, hospitals, laboratories and the like, greatly need a sympathetic understanding on the part of the general public.

As I have tried to indicate, any attempted solution of this important problem must be tentative on account of the rapidly changing conditions of medical practice. One must recognize and make use of certain trends in medicine and, in my opinion, it is not necessary in so doing to compromise the broader aspects of the necessity of public service on the part of the profession. It would seem, therefore, wise and expedient to recognize the important principle of the full-time physician or surgeon and to attempt to gain the advantage of that principle without sacrificing the other principles involved. It will be desirable that no inflexible standards be adopted, because it will be well to study the development of many plans in different communities. Again, there will always be very special situations both in regard to local conditions and special foundations for which such solutions must be made. I have already referred to the Mayo Clinic. I might mention the Hospital for Medical Research of the Rockefeller Foundation and certain rural community hospitals, as special types. To my mind, however, it would be a mistake to separate into distinct groups those hospitals which do undergraduate teaching and those hospitals which do not teach medical undergraduates. There will of necessity be some slight difference in hospitals, but they all have in common the care of the sick, the development of medical investigation, training and teaching of internes, the training and teaching of graduate physicians, the training and teaching of their respective staffs, and community co-operation in its broadest sense.

Nearly all hospitals of any considerable size have accepted the principle of full-time physicians and surgeons for the interne period. That the principle of the full-time physician and surgeon should be extended beyond this one aspect is my strong belief. I believe that above the grade of interne specially qualified men should be encouraged to continue intensive full-time work for a varying period. I believe, furthermore, that on the grade which is generally designated as the visiting staff there might well be a full-time man, upon whom would fall much of the responsibility of the executive work of the professional staff which does not belong to the hospital superintendent or director. In a hospital which concerns itself with the teaching of

undergraduate medical students such a full-time doctor might well be either the professor of medicine or surgery or the executive officer of that department. Similarly, in the hospital which does not do undergraduate teaching such a full-time man might either be the head of one of the services or perhaps the executive officer of one of the services. Under his direction would naturally come the problem of developing medical investigation within the walls of the hospital. In this way it would be possible to create a more effective professional administration than is now usually possible with a completely part-time staff. In this proposed arrangement the large majority of the staff will be part-time doctors who will bring to the clinic their experiences and their contacts in private practice and who will take away to the community at large their hospital experiences and their hospital contacts. In my opinion it certainly would not be well to restrict the visiting staff merely to men who do only office or consultation practice. It would seem desirable to have representatives of all the different groups on the staff. It would probably happen that there would be rather frequent changes in such a relatively large staff, both in the full-time personnel when the younger full-time men go into varying kinds of practice and in the part-time personnel when active hospital work is no longer mutually advantageous to the hospital and physician. I dwell for a moment upon the importance of these occasional changes, because, as is well known, to those familiar with the hospital situation, there not infrequently arises a situation in the case of any individual doctor in which the exchange between the doctor and the hospital is essentially negligible. The doctor is so busy that he contributes nothing to the hospital and the hospital contributes nothing to him except a vague sense of pride in being connected with a good institution. Such a situation, familiar to all of us and tolerable perhaps in an exceptional instance, is hardly healthy when there are many instances. A junior man would make very much more of the opportunities than the overdriven practitioner or consultant, and the hospital would be doing a really better work for the community. I yield to no one in my admiration for the busy general practitioner. It is my firm belief that frequently he would do a larger service to the community if he substituted two hours of hospital for two hours of general practice. Unquestionably the hospital needs him. However, in this transition stage, too often the association of the very busy practitioner with the hospital has not been satisfactory. I have strong hopes that in the future some arrangement which is mutually agreeable and beneficial to the hospital and to the busy practitioner can be evolved. The recognition on the part of hospitals that they must serve the entire community, rich as well as poor, will, I think, help solve this difficulty. But I would indeed be sorry if the hospital development

should take such a form as to change this same very busy private practitioner into a full-time hospital practitioner.

Most successful medical men unconsciously or deliberately restrict their activities, although often not in the number of hours of work a day. One cannot entirely disregard time and distance even in a motor car. It is entirely feasible, even if not always easy, for the busiest practitioner to secure some daily free time. There comes up, of course, the obvious suggestion of part-time salary, particularly for those men who apparently subtract from their income for every moment spent at the hospital. I am not prepared to be dogmatic on the subject of part-time salaries for clinical men. It is bound to be tried out very extensively, because it is such an obvious compromise. To my mind, however, the part-time salary should rarely be a permanent arrangement. The holder ought to be passing to whole time with a larger salary or part time without salary. There will always be important exceptions, but in general two points have already been clearly demonstrated. First, the physician is abundantly repaid indirectly from his association with the hospital; second, the salary does not seem to be a very important factor in increasing the value of the part-time work. It depends on the man, not on the salary.

There is no one who appreciates more than I that such a plan as I have tentatively and vaguely outlined would not always be easy to operate. Furthermore, such a plan in the recognition of the desirability of even a moderate extension of the full-time and salary principle means increased financial expenditure on the part of the hospital. I by no means minimize the financial burdens of the hospital when I recall that somehow the money has been forthcoming for other innovations of proven value, as, for example, the expensive x-ray equipment, perhaps even radium, and often the salary of the x-ray specialist. The difficulties of this general plan are not insurmountable, provided that there is a frank recognition of the dual principle involved and provided that there is an adequate recognition of the fact that the hospital has a responsibility in the largest sense to the community and that in the adoption of a necessary principle in the trend of full-time medicine, it at the same time adopts the equally important principle that the part-time physician plays an equally important rôle, and that his position, while different, is equally dignified and equally vital to the success of the hospital and to the continued esteem of the hospital in the eyes of the profession and of the community.

DISCUSSION.

DR. H. A. CHRISTIAN, Boston: I agree so thoroughly with what Dr. Lee has said that there is very little to discuss. In his plan of development it seems to me perhaps worth emphasizing that there is a considerable place for part-time men with part-time salary. I think there are more men who do hospital work who should receive a salary remuneration. I

don't believe that they should be pushed to the point of paying everybody per hour for work, or anything approaching that, but I think there are a great many of the younger group of men who are extremely valuable to the hospital. Of course the hospital is valuable to them, but in order to live and develop, they need a certain amount of financial aid and I think the hospital should provide a part of that. It is the same in the medical school, where the unpaid teacher has not always been a great success.

Now in the whole-time plan, but little attention has been given to the ageing of the whole-time man. I have an idea that the whole-time man is more like champagne than sherry, because he does not improve as time goes on, but is apt to become "flat." As Dr. Lee has suggested, he is extremely effective in the hospital organization, because of many reasons, but as time goes on I think he tends to show very much the lack of contact with the community, and consequently his earlier efficiency decreases in a different ratio from the efficiency of the part-time man, who is constantly in contact with the general public in some form of private work, or practice.

So my feeling has always been that the whole-time man, even in the strictest sense, should be whole time for a comparatively short period of time, and then give way to some one else in that job and shift over to a more definitely part-time arrangement with the hospital, probably on some sliding scale.

I feel very confident that it is extremely easy for the man who works solely in the hospital to gradually slump on the job, as most professors do. It is always a great problem in the university to take care of the man who has become less efficient, because he has become a little lazy and medical men are not unlike other people in that phase of the situation. It is one of the undesirable features of the whole-time scheme. A part-time man is not so apt to become lazy because of the necessity of hustling to pay his necessary expenses, and the whole-time man is not confronted with that necessity.

I think it is a very interesting fact that long before we heard much about the general discussion of whole-time teachers in clinics and whole-time hospital men, the process was well under way and the hospital had a number of whole-time men, so that it is not a new thing but a gradual evolution that has taken place. The problem is how far it shall go in one direction and how far in the other.

I think Dr. Lee has very admirably sized up the situation and has given a very good outline of the desirable relationship between the whole-time and the part-time workers.

DR. P. W. GOLDSBURY, Deerfield: In line with what Dr. Christian has said about a man's growing stale, I heard a recent discussion about the full-time and part-time health officer, and one, who was upholding the policy of part-time health officers told of his experience in a certain State of which he was health commissioner. He dwelt on the trouble he had in taking a full-time health officer, well trained, from the eastern part of the country and having him put into the State over which he was health commissioner; and the difficulty that that health officer had in interpreting himself to the people. It seems to me there is an analogous situation here, as applied to the case of a man who is a full-time hospital man getting where he cannot interpret himself to the people of the district which that hospital is to serve. I think it a very important point to keep in touch with the people.

DR. LEE (closing): Probably Dr. Christian and I are entirely agreed about the part-time individual on the part-time salary. I feel that this particular development may be a good deal of a menace, and that is the reason I rather decry it. I think under special circumstances that the part-time salary man in the hospital may be very desirable, but as I tried to point

out, I feel that it should be largely a transitory arrangement. In comment on Dr. Goldsbury's remarks, I do not accept the analogy between the part-time health officer and part-time physician.

Original Articles.

THE REGISTRY OF BONE SARCOMA AND MEDICAL HUMAN NATURE.

The readers of the BOSTON MEDICAL AND SURGICAL JOURNAL may be interested in the replies to the questionnaire postal which I recently issued, in order to find the number of cases of bone sarcoma now resident in Massachusetts.

The following are the two letters which I wrote to the JOURNAL concerning this matter:

February 2, 1922.

Mr. Editor:

I wonder if you would give me your help in obtaining some statistics for the registry of bone sarcoma? It is desirable to know the frequency of occurrence of cases of this lesion and there are no statistics by which we can obtain it. It occurred to me that a pretty accurate estimate could be made in the following way:

According to the directory of the American Medical Association (1918) the population of Massachusetts is 3,662,329 and the number of physicians 5494. If each one of these physicians should drop me a postal saying either "I do know" or "I do not know of a case of bone sarcoma at present alive in Massachusetts," we should have, almost by return mail, the best information in the world on the percentage of this disease per capita of population.

Of course I realize that your JOURNAL, interesting and instructive as it is, by no means reaches every physician in the state, and that many of those whom it does reach do not read everything in it. Nevertheless, there seems to be a way to counterbalance that discrepancy. If every physician who *does* read this letter will constitute himself a local committee for a week and ask every other physician he meets during that week whether he knows of a living case of bone sarcoma, and obtains their signatures, I believe we should reach nearly every physician in the state. These could be checked off in the directory and I could make a personal appeal to the remainder.

I believe that every doctor in Massachusetts would be glad to contribute his bit to medical science, if the doing so did not involve too much time and expense. This plan would involve but a minute of time and a cent apiece, so the main thing would be to get the plan to them. Will you try it? They will each do their bit if you do.

A few words about the registry may not be out of place. The registry of bone sarcoma aims to be a combined national study of the diagnosis

and treatment of this lesion. Although organized independently by Dr. Bloodgood of Baltimore, Dr. Ewing of New York and the writer, it is now a committee of the American College of Surgeons. Our object is to register every case of bone sarcoma and by following the cases (through their medical attendants) to learn what the result of each is and what, if any, forms of treatment are effective. At present these cases are too rare for any one surgeon or clinic to obtain a sufficient number for study. We do not expect to find an excessive number in the whole country. In fact, during the year and a half in which we have been collecting cases we have only found four five-year cures by amputation, and altogether only under one hundred cases which are now living, including those known to be moribund.

If the physicians of Massachusetts will promptly send in the postal cards, negative and positive, as above suggested, we shall at least know what the problem is in this state. All supposed-to-be bone sarcomas should be reported, including giant-cell tumors, except epulis. We want to know of all cases now alive whether cured, under treatment or moribund. We want negative answers as well as positive.

When we once know who has charge of each case in Massachusetts we can communicate directly with him and perhaps by showing our collection help him to treat his particular case more satisfactorily. We can at least give him expert pathologic opinion on sections of tissue. We should be glad to demonstrate our collection to anyone interested.

I hope, Mr. Editor, you may see fit to publish this letter, although I fully realize that it may be a precedent you do not care to establish. I ask the favor because our committee represents a great national association which has undertaken this intensive study of a rare and singularly fatal disease. The work of the committee consumes a great deal of time and I hope that you and your readers will help us out.

The American College of Surgeons holds its clinical congress in Boston next October. I hope we shall then be able to state the exact number of cases of bone sarcoma in Massachusetts, with pathologic proof of each case if it is obtainable.

Should this letter be read by physicians outside of Massachusetts, I may repeat that this investigation is a national one, and we should appreciate any positive reports of cases. It is only in Massachusetts that I am trying to get *negative* as well as positive replies.

(Signed) E. A. COOMAN, M. D.

February 27, 1922.

Mr. Editor:

I wonder if the result of my letter in your issue of February 2 would interest your readers? My letter was intended to enable the registry of bone sarcoma to find out how many cases of bone sarcoma were known to be living

in Massachusetts, whether cured, under treatment, or moribund. It suggested that if every one of the 5494 physicians in this state would drop me a postal stating whether or not he knew of a case we should have at once the best statistics ever obtained on the frequency of bone sarcoma.

In reply I have had up to date *only seventeen negative and two positive answers*. Is this because your Journal is not read or because of the indifference of the medical profession as to whether the frequency of bone sarcoma is known or not?

Perhaps your readers may be interested in the human nature problem involved, even if they are indifferent as regards the advance of medical science. Your editorial board may also be interested to know what proportion of your 3546 subscribers in Massachusetts read the JOURNAL thoroughly. I therefore enclose a diagram which aims to analyze the problem.

If you are interested enough to publish this letter and diagram in three successive issues I will undertake to send a return postal to every physician listed as living in Massachusetts, in the directory of the American Medical Association, who has not dropped me a postal a week after the third issue. On one-half of the postal I will have this diagram printed; the other half will have the return address to me. Eventually you can publish the diagram with the numbers following each heading. This will give the facts to the few interested in bone sarcoma and the many interested in the BOSTON MEDICAL AND SURGICAL JOURNAL and in the psychology of the medical profession.

(Signed) E. A. CODMAN, M. D.

Everyone is interested in human nature, even if not in bone sarcoma. Each of us thinks he knows something of the human nature of his fellow practitioners in Massachusetts. Here is a chance to test ourselves. Let each reader of this article make his guess of the number under each of the headings on the postal and then compare with the text. Whether astute politicians or professional psychologists would be best qualified to answer these riddles I do not know, but a wise man should be able to do so better than a mere "guesser."

Undoubtedly in sending this questionnaire I have added to the many annoyances which afflict the modern practitioner. One writes as follows, expressing his "amusement at the solemn earnestness with which a statistical study of bone sarcoma developed into an intensely serious tabulation of physicians. No serious soul with a burning missionary zeal appreciates that when he asks a general practitioner to pause and give him his facts he is one more of a horde of modern complications that are wearing on our patience. We are beset by telephone, by mail, by interviews by social service sleuths, family welfarers, accident and health insurance certifi-

DIAGRAM.

3546 PHYSICIANS IN MASSACHUSETTS.

LETTER ON REGISTRY OF BONE SARCOMA IN BOSTON MEDICAL & SURGICAL JOURNAL, FEBRUARY 2, 1922.

Please reply to this by consecutive numbers, e.g., 1—4—15 means "I have read or heard of the Registry and did not reply because I have retired from practice"; 2—6—8—16 means "I have not read nor heard about the Registry of Bone Sarcoma and do not subscribe to the Boston Medical and Surgical Journal from motives of economy."

Dear Doctor:

May 1, 1922.

The Registry of Cases of Bone Sarcoma wishes to obtain for statistical purposes the number of cases of this disease at present alive in Massachusetts.

The letter referred to asked each physician to reply as to whether he knew of a case now living, whether cured, under treatment or moribund.

We shall be very grateful if you will state on the return postal whether or not you know of a case, and also give us the facts called for in the above scheme. Negative as well as positive answers are solicited.

E. A. CODMAN, Registrar.

RETURN POSTAL.

I do—do not—know of a case of bone sarcoma at present living in Massachusetts.

My reasons for not replying to your letter in the BOSTON MEDICAL AND SURGICAL JOURNAL were:

(Signature)

ates, workman's compensation documents, lawyers' letters, etc. These time-consuming, insistent nuisances have multiplied most horribly in the last ten years. The end is not yet, because now the soldier and, especially, the almost soldiers, are just beginning a drive for bales of affidavits to bolster up claims, many of them bogus." However, he did his bit and said he did not know of a case of bone sarcoma!

Another wrote that he was no more interested in bone sarcoma than I was in knowing "how many flies could light on a golf ball." But he, too, did his bit and said that he did not know of a case. There were other interesting replies, but none were so depressing as those who did not reply at all, for they spoiled the statistics.

Evidently the postals were received in very different spirits by different individuals according to their views of life in general. Dark suspicions of the intentions of the writer were probably held by some who promptly dropped the postal into their waste basket. Pity for my

wasted optimism probably indolently slipped the card into other waste baskets. Rebellious feelings against the unfairness of modern life may have made others tear the card to bits. One may speculate indefinitely as to the motives that inspire men to make decisions—even trivial decisions—but if you, reader, understand the psychology of your fellow practitioners in Massachusetts, write your numbers under the various headings.

My motives, so far as one can understand his own motives, were in fact to interest the practitioner in this study, so that when the American College of Surgeons meets in Boston next fall I can state that every case of bone sarcoma has been registered and that whatever treatment the patient is undergoing, every case in Massachusetts is being put on record for the benefit of future sufferers with this disease. Financially I have nothing to gain, for no charge is made for the services of the registry.

Personally, I should gain something—success in a difficult task is something anyone enjoys briefly. If I can collect all the cases in Massachusetts my committee can collect nearly all the cases in the United States and make a study of this disease, which will be really worth while. If we know the number in our 4,000,000 population in this state we can at least estimate the magnitude of our problem.

And if I can show that Massachusetts is keeping a record of every case that her physicians and surgeons are experimenting upon, I shall have an example to set before the world. These patients *must* be experimented upon. Shall we set the example of recording the results of these experiments or shall we continue to let these patients be exploited by hospital "authorities," self-constituted "experts" and "successful" practitioners?

If any honest physician, whether he be chief of a great surgical service or an underpaid, overworked practitioner, is treating one of these patients fairly he will not be ashamed to record the case or to inform the patient or his friends of the existence of the registry collection, and to give the patient the benefit of his own study of the other cases already registered. The registry will be glad to have anyone who is treating a case of bone sarcoma study its material. The collection is public property, under the guardianship of the American College of Surgeons. The writer is the unpaid registrar and would regard it as his duty to demonstrate the collection to any one who registers a case.

My objective was twofold. First, to let every physician in Massachusetts know of the registry of bone sarcoma and what help it could be to patients with this lesion. Second, to locate every case of bone sarcoma in the state and get the co-operation of the physician in charge of each case. How far have we succeeded?

In the first place it is impossible to accurately determine the number of physicians in the

state. The State Board of Registration in Medicine keeps a file of those who have been registered, but does not make an active file, deducting those who die or move away or even those who move into the state and do not register (unless complaint is made). The directory of the American Medical Association for 1921 gives the number as 5959. This figure is, of course, out of date, but is probably the best available. Return postals were sent to 5577 of these, leaving out some of those marked "retired" and "specialists." Of these 157 were returned "unclaimed," "dead," "away" or with no notation at all. This leaves 5420.

Of this number we have heard from 2230 as to the main question of whether they knew of a living case of bone sarcoma. Only 115 answered positively, and by cutting out duplicates we have only located 71 possible cases of bone sarcoma. We are still endeavoring to get detailed proof of these.

So as to letting the physicians of the state know of the existence of the registry of bone sarcoma, we can be fairly sure we have reached two-fifths of them and probably most of them. As to whether we have located all the cases of bone sarcoma we can be a little more optimistic. I think it is a fair assumption that a physician who knows of a case would be apt to reply to the card and that one who did not would not bother to send negative evidence.

Now with regard to the other questions on the card which have no relation to bone sarcoma, but to medical human nature. This might be called a study in "bother."

Only 56 bothered to answer the first two letters. Only 2230 bothered to answer the postal.

Only 658 of these bothered to state they had read the letter and give their reasons for not answering it.

Admitted inertia, procrastination, not interested, or having failed to realize that the statistics necessitated negative as well as positive answers.....	377
Thought they had previously replied....	30
Thought their answers were not desired because they were specialists.....	121
Thought their answers were not desired because they were retired.....	71
Did not reply because of personal or other reasons.....	53
Expressed disapproval or opposition....	6
	<hr/> 658

This leaves us still in doubt of the state of mind of the 3190 who did not bother to reply at all. Certainly the opposition cannot be strong if only six bothered to express it.

Concerning the question as to how well the BOSTON MEDICAL AND SURGICAL JOURNAL is read, 1026 bothered to state that they had not read my letter. Of these 1026, 243 bothered to state that they subscribed to the JOURNAL and 273 that

they did not subscribe and 21 bothered to say that they wished to subscribe! Whereas 510 of those who bothered to answer that they had not read the letter did not bother to state whether they were subscribers or not. This is a refinement in the degree of bother.

What is the state of mind of the 3190 who have not helped me with their answers? Is there opposition or only extreme indifference? Surely each must understand that negative replies are necessary for reliable statistics. Only six of the 2230 who answered have expressed opposition or disapproval. Five simply stated "disapproval" and only one gave a reason: "Your method in gathering your data has antagonized rather than elicited my interest in your study. Your data could be obtained in a more dignified and constructive way, I believe." This is the only criticism I have had, yet this critic did not neglect to do his bit and stated he did not know of a case of bone sarcoma.

The reason for mixing up the other questions with that on bone sarcoma was that I believed the total would interest a larger number of men and I should thereby gain my two chief objectives of getting the registry known and of finding out the actual number of living cases. Perhaps the author of the criticism understands medical human nature better than the writer. So far as I know no one has ever attempted to gather statistics in this way before and some method had to be chosen. As chairman of the committee I have expended \$135.25 in this effort and it remains to be seen whether the regents of the college will feel that I must bear the expense personally or that I should be reimbursed. To my mind the importance of making the study complete can hardly be measured in dollars. I may be criticized for expending this money in this way, but no member of the American College of Surgeons would be criticized for charging this amount for the simple operation of amputating a limb for a patient with bone sarcoma! Yet the facts which this registry of bone sarcoma have already collected show that few if any surgeons are qualified to decide whether a limb should be amputated in any given case or not.

Perhaps it is because the medical profession realizes that this plan of registering every case of bone sarcoma for thorough study is an epitome of the just criticisms of our methods of surgical practice, that they distrust it and are disinclined to do their bit to aid me in gathering my statistics. Or is it just dead indifference?

If there is any real opposition one would think that more than six of 5577 to whom the postals were addressed would express it.

Will some wise man *show me* (not *tell me*) how to reach the other 3190 necessary to complete my statistics? I have expended all the money I think it is right to expend for the college on this questionnaire, but I believe I could

obtain from private sources a like amount to be spent on a better method.

THE TREATMENT OF ASTHMA.*

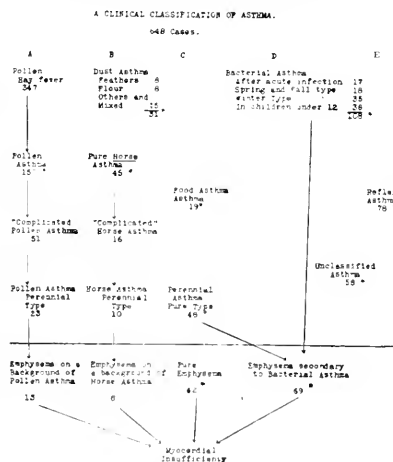

By FRANCIS M. RACKEMANN, M.D., BOSTON.

Physician to Out-Patients, Massachusetts General Hospital.

[From the Anaphylaxis Clinic of the Massachusetts General Hospital.]

MANY methods of treatment have been devised and described for asthma. Each one of these methods is of great use in certain cases, but no one of these methods will cure every case. This simply emphasizes what we know already—namely, that there are many different kinds of asthma—so many in fact that it is entirely reasonable to regard asthma as a symptom and not as a disease entity and to define the word "asthma" as a peculiar type of dyspnea. According to this definition it is quite obvious that there is a considerable variety of cases. Thus there are not only typical cases of asthma of the extrinsic type where symptoms occur only after exposure to the particular foreign protein cause, but there are many other cases in which there is no such apparent cause and yet which during the attack present quite the same clinical picture as the first group. Still other cases have a chronic bronchitis, and finally, there are here included cases which have the typical barrel-shaped chest and the chronic cyanosis of pulmonary emphysema. Cardiac asthma has not been consciously included.

The various kinds of asthma are shown on the accompanying chart. This chart has been

*Read before the New York Academy of Medicine on April 15, 1922.

found to be very convenient in studying individual cases as it indicates not only five important groups, but also shows how the character of the disease in the individual patient may change. This change is due to bacterial invasion, probably in most cases of the bronchial mucosa, so that beginning with a simple protein asthma we have first a simple complicated asthma and later a more advanced type, finally associated with chronic pulmonary emphysema, the symptoms of which are perennial and which appear to bear little if any relation to the original cause.

In a recent review of 648 cases¹, foreign proteins were considered to be the underlying cause of asthma in 38%. Just as these 38% of sensitive cases can be subdivided into groups, so also can the 62% of non-sensitive cases be subdivided more or less into groups. I have designated some of these cases as bacterial asthma and others as perennial asthma and another more important group as reflex asthma.

In this connection the diagnosis of bacterial asthma is made partly by excluding foreign proteids as causes, but on the other hand it is made also on the history. Several cases have developed asthma immediately following some acute respiratory infection. These cases have considerable cough and raise definite amounts of sputum, so that it would seem entirely reasonable to regard bacteria as responsible. Another group of cases has attacks of asthma in the spring and fall but during the summer and winter are entirely well. Their attacks come on in spite of the fact that they lead exactly the same sort of a life in exactly the same locality and, therefore, it is hardly reasonable to assume that protein sensitiveness can be a cause, especially since during many months in the summer and also in the winter they are entirely well.

Similarly, the cases of winter asthma are assumed to be largely bacterial in nature. Here again foreign proteins could hardly be important, although it is conceivable that by living more indoors behind closed windows the dose of some particular dust or odor might be larger.

The diagnosis of bacterial asthma in children is apparently confirmed by the fact that in most cases vaccine therapy really does prevent the onset of "colds" and thus definitely relieve the asthma and all this without any changes in diet or mode of living.

The term perennial asthma is undoubtedly artificial and simply includes those non-sensitive cases who have symptoms at all seasons without any apparent cause.

The diagnosis of reflex asthma is made largely on the recognition of pathology elsewhere than in the lungs, treatment of which by surgery or otherwise often relieves the asthma.

So far as diagnosis is concerned, it is the experience of the writer that the history is by far the most important part of the study. A pa-

tient with late hay fever develops asthma in early September; this asthma hangs on until after the first frost, perhaps until November. The patient is worried because two years ago the asthma stopped in late September when the hay fever stopped. If we conceive of a pollen asthma complicated by bacterial infection such a history is easy to explain.

In view of the foregoing it is obvious that the treatment of asthma is really the treatment of the cause. It is beyond the scope of this paper to discuss the technic of pollen treatment but it is important to recognize in these so-called complicated cases, and particularly in the perennial cases, that pollens are the underlying factor and hence the next season should witness a very determined effort to desensitize the patient so as to prevent the onset of the usual train of symptoms and the continued progress of the disease, because when once chronic emphysema has developed, no treatment is really satisfactory.

Like the pollen cases, the animal dander and other dust cases are susceptible to specific treatment. In these, however, we are much more fortunate in being frequently able to remove the offending substance from the patient. It is not unlikely that such an avoidance of the specific cause may bring about a spontaneous rise of tolerance or desensitization. Schloss² speaks of cases with a spontaneous and temporary desensitization. Recently a patient said that he used to have horse asthma as a child; has been entirely well for many years until he went to the circus and had another attack. The several years' freedom can, of course, be interpreted as due to an increased, but not an absolute tolerance, since symptoms did follow when the dose of the offending dust was large.

The author's personal experience with the treatment of horse asthma with horse-hair extract has been far from satisfactory. A variety of extracts, all of which give beautiful tests in horse-sensitive patients, have been used, but in most of these cases it has been quite impossible to increase the dose above a certain small maximum, not only because the local reactions following the subcutaneous doses were large, but also because severe symptoms at times supervened. One case, however, has been cured, since she has had no asthma for nearly three years. In her case it *was* possible to increase the doses slowly but steadily. Her skin test, done recently, still shows a positive reaction to horse dander.

The subject of vaccines in asthma is indeed a large and important one. Theoretically, at least, vaccines act specifically to stimulate the organism to overcome the invasion by a particular bacterium. There also is a non-specific effect probably due to a non-specific mobilization of specific antibodies, as shown by Hektoen, Bieleing, and others. And finally there is the psychic effect of doing something definite for the patient—a feeble argument for vaccine ther-

apy, but in certain cases a justifiable argument.

Before discussing the indications for the use of vaccines, there are these contraindications: Vaccines should never be used until a careful study has been made; until foreign proteins as possible factors have been carefully considered, and until possible foci of infection or other lesions have been removed or treated. Vaccines should never be used if there is a fever. As has been just said, however, a foreign protein or extrinsic asthma of any type may be complicated by bacterial infection, and in certain cases vaccines can be given, for example, together with the protein treatment. For example—the perennial type of asthma based perhaps on pollen sensitiveness and proved not to be caused by other foreign proteins may be treated temporarily at least by vaccines.

Direct indications for vaccines are few. There is a considerable group of children who have asthma associated with colds—in other words, asthmatic bronchitis. Treatment with vaccines is really worth while, particularly if the attacks are separated by definite intervals so that organisms isolated in one attack can be used in a vaccine to prevent the next. Likewise, in adults, there are many cases whose asthma occurs at relatively long intervals in definite attacks, also preceded by colds, and in these cases, too, vaccines are a reasonable treatment. In adults over forty years old it is quite common to see asthma which may be designated as “winter asthma,” since these individuals are perfectly well in summer, and in whom the first respiratory infection of the autumn is very shortly followed by asthma which troubles them with wheezy breathing and dyspnea on exertion throughout most of the winter. In these cases the symptoms are not always severe, most of them raise more or less opaque sputum and the clinical picture is one of a sluggish, low-grade bronchial infection associated with wheezing. In these cases, likewise, vaccines are worth trying and often do good.

As to the *technic of vaccine therapy*. The sputum or other material is smeared directly over the surface of a rabbit-blood agar plate. Various types of colonies are identified, isolated in pure culture and transplanted usually to dextrose broth. Vaccines made in the usual way are roughly standardized (according to the opacity of the suspension) so that one cubic centimeter contains about one billion organisms. From each case four or five individual vaccines are made. The selection of the particular vaccine is based upon the observation, which has been repeatedly confirmed, that vaccines in asthma do good only in case some local reaction follows their subcutaneous injection. A quarter of a c. c. or about two hundred and fifty million bacteria of each vaccine is injected subcutaneously. In twenty-four hours it will usually be found that one or perhaps two of the injection sites show a red area, varying in diameter

from one to two inches, which is slightly swollen and tender. The other sites may show a trifling redness or nothing. No attention is paid to the reaction until after eighteen or twenty-four hours. The vaccine producing this local reaction is the one selected for treatment. If two sites show a redness, the two vaccines are both used but are injected separately, so that further reactions to their injections can be studied and compared.

As regards *heterologous vaccines*. It is very important to observe that in a few cases where autogenous vaccines have been made, that subcutaneous injections were made with heterologous vaccines as a control to the autogenous. In a few of these cases such heterologous vaccines gave reactions which were as large, or larger, than the autogenous and, under these circumstances, it has been frequently found that treatment with the heterologous vaccine has brought about satisfactory results.

As to whether one particular vaccine is more apt to produce a positive reaction than another, it may be said that there is no one type of vaccine which invariably produces a positive reaction. A green-producing streptococcus may react in one patient and give relief when used in treatment in that patient, while in another patient there will be no local reaction at all. In the same way hemolytic and nonhemolytic, white and yellow staphylococci may or may not give a reaction. This indicates that the reactions depend upon some peculiarity of the patient and not of the vaccine. The important point is that whatever the vaccine producing a local reaction, treatment with it will almost always do good.

In treatment, doses are given at intervals of five to seven days and are graded according to the local reaction which has followed the previous dose. However, additions to the previous dose are rarely made more than two-tenths of a cubic centimeter, so that after six doses the patient is receiving a dose of about one and a quarter billion and this provided local reactions have not been too large. I would emphasize the importance of a local reaction by saying that it is all too common to have an injection of vaccine followed by no local reaction at all. Under these conditions the dose can be doubled at the next visit and perhaps thereafter doubled repeatedly without producing any local reaction and without making the patient better or worse. On the other hand, when an injection of vaccine does cause a local reaction, further doses will in most cases do good. If these doses are pushed too rapidly, the asthma is often aggravated to a definite extent—a phenomenon perhaps comparable to the focal reaction which occurs after the injection of many specific and non-specific substances.

In those cases where vaccines bring about relief, this relief usually occurs before six or seven doses have been given, and it is very doubtful whether it is worth while to continue the re-

peated injection of that particular vaccine beyond this point without clinical results in the meantime.

As to the results of the use of vaccines. It is very difficult to estimate results; replies to questionnaires are only fairly satisfactory, not only because the patient's statement is the only check, but also because most of the patients are taking potassium iodide or other remedies or are modifying their life in some way which in itself is important. However, an earnest effort to discover the value of vaccines has shown the following:—Autogenous vaccines have been used in one series of 32 cases, including all types, with good results in 24 cases. Heterologous vaccines have been used in another series of 17 cases with good results in 11 cases, so that it is quite evident that the use of vaccines is worth while. However, these good results are by no means always permanent. It frequently happens that whereas during one winter the patient was treated with some success, attacks will occur during the following winter and further treatment, starting over again with fresh cultures must be undertaken.

The general treatment of the asthmatic must never be overlooked. In looking over the reports turned in from a recent questionnaire, it was quite gratifying to find that of those cases heard from practically all originally classed as reflex asthma were definitely improved. Fifteen of these reports were from children in whom efforts to improve their malnutrition, bad hygiene or improper methods of feeding constituted the only treatment. All fifteen were markedly improved.

One of these children was a tall, pale, thin faced girl of nine who had been having asthma in regular weekly attacks, usually on Sunday, for several months. On the advice of the family doctor, milk and eggs had been withheld from the diet. The child was obviously underweight. The chest was long and thin, with rounded shoulders and projecting neck and head: the front chest was quite flat and the abdomen was prominent. Skin tests were done, found negative, and later repeated in order to satisfy the mother that the child could take all foods without difficulty. The diet was rearranged and balanced properly. Her school lunch was adjusted so that she had two hearty sandwiches and no cake. Regular play and exercise out of doors was insisted on, and, in addition, arm and chest exercises were prescribed. Hydriodic acid was given temporarily. When seen a year later the child had had only two attacks in the previous four months and had gained a great deal in weight and strength.

Another child was a small boy of ten. Asthma had existed since infancy and in addition he suffered from attacks of syncope and convulsions, strongly suggesting epilepsy. He was distinctly "queer" mentally. During these attacks he had never injured himself nor did he

lose control of his sphincters. He was a very "spoiled" child. He was round shouldered and in very poor general condition. In spite of the possible epilepsy he was given corrective exercises and was put on a very rigid daily regime and schedule, including plenty of time out of doors. Within a month the epileptiform seizures had practically disappeared. He had gained one inch in height and several pounds in weight and his asthma, while not entirely gone, was improved to a marked degree. There was no other treatment beyond measures of general hygiene and careful mental control.

Tonsils were removed from four other children, with good results in three. In six adults bad teeth, infected antra or bad tonsils were treated surgically with good results in four. One of these is a striking case. A girl of 26, she had severe and almost constant asthma for ten years. Her tests were all negative, and in the hospital ward she continued to have severe attacks for over three weeks, in spite of all treatment, and was discharged in poor condition. Later, in the outpatient department, a pansinusitis was finally recognized, and following a left Killian operation, she was free of all asthma for nearly six months; and then, following a slight return of her symptoms, the other side was similarly drained, and she is today having some asthma, but in very mild form, and the hope of curing her is reasonable. She has gained nearly twenty pounds in weight.

Two patients had a positive Wassermann, one was treated with arsphenamin and so far is very much better. The other had not returned for treatment and the asthma is the same. In four patients, asthma was probably dependent upon overwork or excessive mental worry, as forced rest, both mental and physical, has cured two of these patients. Two patients with visceroptosis have had no asthma since wearing a proper abdominal belt.

Several patients have been advised to move to another climate. One of these, an Italian laborer, was sent back to his family in Italy, where he is now well; while in America he had for two years practically constant asthma which remained almost the same in the hospital ward, where presumably foreign protein dust would not reach him. Another, a superintendent of nurses, writes from California that the very severe attacks of last winter, which forced her to bed for several weeks at a time, have gone and she is now well. Results such as these should leave us ready to believe that in certain cases a neurosis may be the underlying basis, although there are always other factors.

Finally, it should be borne in mind that asthmatics often get well by themselves. While there is available no figure to show what proportion of children with asthma recover spontaneously, this figure is probably large. It is interesting that of 222 patients now over 30 years of

age only 18% have had asthma since before the age of 15.

By emphasizing in this paper the importance of the general physical condition of asthmatics, it is by no means intended that attention should be drawn away from foreign proteins and their frequently vital importance to the cause of the disease. In the study of each patient, foreign proteins should always be borne in mind and never excluded without reason. Skin tests should always be done in doubtful cases and these tests should be interpreted logically and perhaps repeated if necessary. While positive skin reactions obtained with reliable test substances are probably always to be regarded as evidences of slight sensitiveness, yet in many cases, this sensitiveness is so light as to be clinically unimportant and such tests may usually be disregarded. Furthermore, the finding of a negative skin test does not always rule out sensitiveness to a given substance.

However, skin tests alone are by no means the only method of study and it is usually true that success in treatment must in each case be preceded by a very careful consideration of the patient as a whole. When the different pieces of evidence are in, their relative importance must be weighed and the whole must be correlated intelligently.

VIOLET RAY IN THE TREATMENT OF VARIOLA.

By PASQUALE ROMEO, M.D., BRIDGEPORT, CONN.

SINCE the time of writing a preliminary note upon the treatment of variola with exposure to the influence of violet ray, I have had opportunity to prove the value of such a treatment in two other cases, bringing the total cases treated by me to three.

Each case was of marked constitutional severity. Two cases were female patients: One 28 years old and the other 37. Both have been successfully vaccinated, but once, when children.

The male patient, aged 26, the first case treated by me with violet ray, had been vaccinated twice with negative results: once when in childhood, again about six years ago, while in the Army.

This case seen in consultation with the attending physician, was at the fifth day of eruption. Patient was covered with a myriad of vesicles all over his body, the face, the palmar and plantar regions. Two vesicles were visible around the cornea of left eye, which was also the seat of a phlogistic process; an epischleri-

tis, causing intense lachrymation and photophobia. The other eye was slightly congested.

The onset of the disease was a typical one, with chill, general malaise, vomiting, nausea, headache, lumbar pains, sore throat and fever, ranging from 105 and 106 F.

Delirium was also a prominent symptom.

The family physician, although hesitant about giving a diagnosis, was inclined to regard the case as one of influenza.

The examination of the respiratory tract was negative and there was no indication of any other trouble which might account for the high temperature.

Four days later the fever came down to 98.6 F., while only three little macules were manifested on the forehead.

Patient paid no attention to it and went to work as usual. Two days later, on rising in the morning, he found that his chest and his arms were covered with a large number of macules. Being frightened he remained in bed and summoned his doctor, who diagnosed smallpox.

Next day all the surface of the body was covered with macules.

When I saw the patient he was very restless and uncomfortable.

He could not lie comfortably, could not use his hands, could not stand on his feet, could hardly eat because of the number of vesicles around his lips and was distressed on account of the general skin irritation.

Nervous prostration was very marked and the patient pitifully asked to be relieved of his suffering.

Opiates, bromides, chloral, absorbent powders, anti-septic lotions were tried with very little benefit.

Knowing that violet ray has been proven to have a place in the therapy of certain skin diseases, I suggested the use of a Menin violet ray lamp, 110 voltage.

Results were gratifying and beyond my expectation. Few minutes after exposure to the ray patient started to say: "Oh, it feels fine; oh, it is really a blessing; I wish that all my body could be treated at the same time; it is so soothing."

Patient felt very much relieved and he begged to have the apparatus left with him, which I did.

The following day I and the family physician visited the patient and to our surprise we noticed a marked improvement in the clinical picture. Patient reported that he slept well for the first time after five days and nights. He could hardly find suitable language by which to thank us for the almost immediate relief afforded him.

All vesicles were dried up and the patient could eat and was able to sit on a chair and move around a little.

The distinctive variola appearances had faded so much, in twelve hours' time, that it really seemed very remarkable.

The initial exposure to the light was of about three hours' duration applied to the whole body. Then patient went to sleep immediately after the treatment.

Treatments lasted for six days and patient applied them as often as he liked, without any rule as to time and duration.

The clinical observation warrants me in stating that—due to the violet ray action—the pustule stage was aborted.

With the exception of some small area, where the influence of the ray did not penetrate, the *restitutio ad integrum* has been satisfactory. Only very small invisible marks remain, at points where vesicles were in an advanced stage.

I saw this patient two days ago and it was hard for me to detect in him any trace of the disease.

The other two cases treated by me were more or less clinically identical. One case was at the seventh day of the disease; the other, at the fourth.

The treatment consisted of exposure to the action of the ray as often as the comfort of the patient required.

The lamp was kept distant from the surface of the body from five to nine inches, according to the tolerance of the patient.

Equally satisfactory results were obtained in the treatment of these other cases.

I devised a way of giving patients the benefit of the ray, simultaneously, all over the body. Three lamps of 110 voltage each were placed on a stand so that the exposed surface extended from the head to the feet.

In this way one lamp radiated the face and the upper part of the chest and extremities; one lamp the abdomen and hands, and the other the feet and thighs. As soon as the patient felt too much heat, and could not bear that sensation any longer, I advised him to turn and expose the other side and so on until relief was obtained.

The lamps were kept from five to nine inches from the surface to be treated, but during sleep I advised keeping the lamp at least one and one-half feet away from the surface of the body.

A large sheet covered the apparatus in order to avoid dispersion of the rays. Good effects were also obtained by using an ordinary single lamp. The only objection I have to make is that one must constantly change the position of the single lamp so that all regions can be treated.

The benefit of the triple combination is greater, because the patient does not need to make any effort in moving the lamp, thus preventing fatigue.

Conclusion: From the experience obtained in treating these three cases I believe that we

have in the violet ray a new and efficient weapon to combat the very distressing sensations caused by smallpox. Furthermore, a powerful agent has been found which, if applied before pustulation has occurred, will almost completely prevent the pox marks.

It seems that the earlier the ray is used the shorter the course of the disease will be, and the constitutional symptoms will be milder.

Considering the great relief which appeared to follow this very simple agent and the inexpensiveness of its application, I believe that this treatment will soon become general.

So far as literature on this subject is concerned, I failed to find any article dealing with the treatment of variola by means of violet ray ever before published.

Medical Progress.

PROGRESS IN SYPHILOLOGY.

By AUSTIN W. CHEEVER, M.D., BOSTON.

THREE CASES OF SYPHILITIC INFECTION DURING LABOR.

LEMHOLT¹ reports three cases of this condition, so far very rarely reported in the literature. In all three cases the fathers of the infants had acquired syphilis sometime during the last three months of the wives' pregnancies, the mothers developing symptoms of syphilis immediately preceding, during, or immediately after labor. Typical chancres developed on the infants' heads, followed by typical acquired infections.

REINFECTION IN SYPHILIS.

Recently there have been increasingly numerous reports of reinfection; Jeanselme and Althabegoity² report a case treated with 300 injections of benzoate of mercury and occasional injections of arsphenamin. Up to the time of the appearance of the second chancre, which was not at the site of the first, he had had five negative Wassermann tests. Treponemata were found in the new chancre. This seems to be a genuine case of reinfection.

EXPERIMENTAL SYPHILIS IN MAN.

Pinard and Lagnignand³ relate the case of a man who inoculated himself with syphilis in order to prove that he had not had it; a chancre appeared in which treponemata were found. He had 8.5 gm. of arsphenamin followed by a negative Wassermann reaction. After two failures he succeeded in inoculating himself again and producing a typical chancre in which treponemata were found, and followed by a papular rash and sore throat. He then had 0.6 gm. of arsphenamin weekly for ten out of twelve

months. Now having a negative Wassermann test, he tried four more times to inoculate himself, at last producing after thirty days a new chancre, followed by a papular syphilide.

THE RESISTANCE (OR IMMUNITY) DEVELOPED BY THE REACTION TO SYPHILITIC INFECTION AND SOME OF THE EFFECTS OF THE SUPPRESSION OF THIS REACTION.

Under this heading Brown and Pearce⁴ describe their results in rabbits of removing the primary lesions; there was a considerable intensification of the disease. Carrying that reasoning over to the human, it would seem not only useless but probably even harmful to remove primary lesions.

EFFECT OF SUNLIGHT ON A SYPHILITIC EXANTHEM.

Much has been written about sunlight in tuberculosis, very little about sunlight in syphilis. Rasch⁵ reports an interesting case of a girl with a lenticular syphilide which failed to appear on the face, neck, and parts of the chest which had been exposed to strong sunlight above a very décolleté gown. He thinks it is the actinic rather than the heat rays that are responsible for this, as it is well known that men exposed to heat, as stokers, have a marked exaggeration of these lesions on the exposed parts.

NEUROSYPHILIS WITH NEGATIVE SPINAL FLUID.

Solomon and Klander⁶ describe and discuss a group of cases of definite neurosyphilis with negative spinal fluids, fitting mostly into the group of vascular neurosyphilis, but also of syphilitic cerebral nerve palsies, cerebral gumma, syphilitic epilepsy, syphilitic spastic paraplegia, syphilitic psychoses. They state that it is often difficult to decide in these cases, which have negative spinal fluids yet with definite clinical evidence of central nervous system involvement, whether they are cases which at no time have positive fluids, and need and often react well to treatment, or whether they are "burned out" cases, cases of former activity, and really only cases of scarring, and consequently to be but little helped by any treatment.

SPINAL DRAINAGE WITHOUT LUMBAR PUNCTURE.

Corbus, O'Connor, Lincoln, and Gardner⁷ have worked out a new application of the previously known fact that intravenous injections of hypertonic saline solutions cause an initial rise in the cerebro-spinal fluid, followed by a fall in this pressure often to below zero, followed by a gradual rise to normal. Apparently the increased osmotic properties of the blood plasma after the addition of the hypertonic solution causes fluid to be drawn rapidly into the bloodstream from all possible sources, including the cerebrospinal fluid.

The technic of the clinical application of this principle is as follows: patients were admitted about 8 A. M., prepared as usual for arsphenamin. At 10 A. M., 100 c.c. of 15% saline solution was given intravenously by the gravity method. Immediately following the injection, the patient is conscious of a feeling of warmth which gradually increases, but never to an uncomfortable degree, and lasts about ten minutes. No food was permitted at midday. After six hours, 0.9 gm. neocarsphenamin was given intravenously. At first all patients were kept in bed for thirty-six hours, but later some were permitted to go home by nine o'clock the same day. In none were there untoward complications. Lumbar puncture may be done without harm if one desires to study the spinal fluid.

VIABILITY OF SPIROCHAETE PALIDUM IN EXCISED TISSUE AND AUTOPSY MATERIAL.

Lacy and Haythorn⁸ report the finding of motile spirochaetae in the blebs on a congenital syphilitic baby kept in a refrigerator twenty-six hours before autopsy: in excised chancre, seven days after removal; in serum from a chancre sealed and kept at room temperature, for 121 days; in saline suspension of rabbit's testicle, both at room temperature and in the refrigerator, for 58 days; inoculation of rabbits' testicles with some of these was positive after 24 hours; attempts at inoculation with completely dried syphilitic material were uniformly unsuccessful.

A STUDY OF THE SPINAL FLUID IN A LARGE SERIES OF CASES OF SYPHILIS IN ALL STAGES.

Wile and Marshall⁹ present an analysis of 1869 cases of syphilis on whom lumbar puncture had been done, and bring out several interesting points, especially the strikingly high percentage of neurosyphilis in cases of syphilitic alopecia, iritis, and pigmentaries of the neck, about 70% to 73% in the first and second groups, about 55% in the third. In spite of the general belief that there is an inverse ratio between cerebrospinal involvement and other forms of syphilis, about 30% of the cases of late syphilides of the skin, bones, and viscera had definite central nervous system involvement. Another interesting point is the large percentage, about 28, of asymptomatic neurosyphilis in the indefinite latent stage.

A NEW LUMBAR PUNCTURE NEEDLE.

Hoyt¹⁰ describes a new needle which is claimed on good theoretical grounds to prevent post lumbar puncture headaches. A needle with obturator similar to the usual type, fitting the Luer syringe, is used as usual up to the point of penetrating the meninges; then the obturator is withdrawn and a much finer needle fitting the Record syringe and enough longer to pene-

trate the meninges is introduced within the larger one. This should tear so small an opening in the meninges that the leakage would be slight or none. It may be used for intraspinal therapy as well.

EXPERIMENTAL STUDY OF THE LATENT SYPHILITIC AS A CARRIER.

Ebersson and Engman¹¹ have made some valuable contributions to the study of latency. From five cases which appeared to have been latent for from one to thirteen years and had either had no treatment at all or none for two years, the authors isolated by rabbit inoculation living treponemata from inguinal glands and semen. Blood and other body fluids failed to give positive results.

WASSERMANN TESTS WITH SECRETIONS, TRANSUDATES, AND EXUDATES IN SYPHILIS.

Klauder and Kolmer¹² found 3 positive Wassermann tests in 19 specimens of milk from known syphilitics; 1 weakly positive in 20 specimens of saliva; 1 moderately positive in 30 specimens of seminal fluid; 5 doubtful tests in aqueous fluid from the anterior chamber of the eye; all of 11 specimens of exudates and transudates were positive; all surface fluids from a number of chancres were positive; all of a number of specimens of saline extract of syphilitic nodules from testicles of rabbits were positive.

THE WASSERMANN TEST PERFORMED WITH CHANCRE FLUID AS AN AID TO THE EARLY DIAGNOSIS OF SYPHILIS.

Klauder and Kolmer¹³ give their technic as follows: when possible they aspirated the surface fluid directly with a fine-tipped pipette similar to a medicine dropper; when not enough fluid could be obtained that way, they placed a few drops of physiological saline solution on the chancre and aspirated the whole fluid after a short time, getting thus a fluid of unknown concentration; yet the results were positive in twelve out of fourteen chancre fluids. Positive results were obtained in a chancre on which a mercurial had been used, making the dark field examination negative, and in which the blood Wassermann had not yet become positive. It is, therefore, a definite aid in the diagnosis of early syphilis.

SILVER ARSPHENAMIN.

The reports during the last year by American syphilologists have not been especially favorable to silver arspenamin. Guy and Jacob¹⁴ report on their use of the drug in 100 cases and consider that silver arspenamin, weight for weight, is more toxic than arspenamin, and in the dosage ordinarily employed is a less effective spirochaetocide. Michelson and Siperstein¹⁵ believe that it clears up clinical manifestations in smaller doses than others of the arspenamin

group, but are doubtful as to other advantages. Fordyce,¹⁶ reasoning from the use of 1800 doses, considers silver arspenamin as a valuable drug because of its greater freedom from reactions, but is not ready to consider it any more curative than other arsenicals, though possibly more active in clearing up early lesions.

THE INFLUENCE UPON TOXICITY AND TRYPA NOCIDAL ACTIVITY OF SHAKING ACID AND ALKALINE SOLUTIONS OF ARSPHENAMIN AND SOLUTIONS OF NEOARS-PHENAMIN IN AIR.

Schamberg, Kolmer, and Raiziss¹⁷ carefully tested out the effect of shaking these drugs for one minute and for ten minutes longer than necessary to complete solution, and found that shaking both the acid and alkalinized solutions of arspenamin increased the toxicity and the trypanocidal activity; that one minute's extra shaking of neoarsphenamin increased the toxicity greatly without increasing the trypanocidal activity, while a ten minutes' extra shaking increased the toxicity enormously. Different lots and brands differed considerably as to their liability to oxidation.

KEEPING QUALITIES OF MARKET SAMPLES OF NEOARS-PHENAMIN WHILE IN THE AMPOULE.

Roth, U. S. Public Health Service,¹⁸ finds commercial neoarsphenamin relatively unstable in the ampoule and suggests that the date of manufacture should be placed on all ampoules and that neoarsphenamin be kept at icebox temperature.

HELIOOTHERAPY IN SYPHILIS.

Hesse,¹⁹ reasoning from the long known beneficial effect of sunlight in tuberculosis, feels that it should be of real use in syphilis: in correcting the anaemia which may be present, in avoiding the possible depressing effect of drug medication, in stimulating metabolism, possibly in helping to prevent involvement of the internal organs, as seems to be the case in tuberculosis. He suggests filling the gaps in drug treatment with heliotherapy.

A NEW TREATMENT OF SYPHILIS WITH TARTROBISMUTHATE OF SODIUM AND POTASSIUM.

Rabell²⁰ reports in the name of Levaditi, bismuth salts as efficacious in the treatment of syphilis. After experimenting on rabbits, he used on 110 human cases of syphilis in all stages subcutaneous and intramuscular injections of tartrobismuthate of sodium and potassium suspended in oil. The only untoward result (and this is frequent) is stomatitis, with an effect on the gums like that of lead poisoning, and closely resembling that of mercury, but much milder, preventable by proper precautions, and easily cured. The urine remains practically normal. He states that it has the

advantage over arsenical preparations of having less toxic effects and also of being prepared with less difficulty and, therefore, more economically. Insufficient time has as yet elapsed for the demonstration of a permanent cure, but the results up to date have been very striking as regards the disappearance of lesions and of spirochaetae. The medicament has been put on the market under the name of trepol, in boxes containing 12 ampoules; each of these contains a dose of 10 eg. per cubic centimetre, in an oily base. The doses are made in amounts of 3 and 2 cc. in a series of 6 injections, the first three containing 30 eg. and the last three containing 20 eg. of the salts of bismuth.

THE TREATMENT OF SYPHILIS BY MERCURY INHALATIONS.

Cole, Gericke, and Sollman²¹ report on an investigation of mercury inhalation in syphilis, very carefully and thoroughly carried out and find that there is no advantage in this method of giving mercury; that it has, on the contrary, a serious disadvantage of indefinite dosage, and the special danger of respiratory irritation.

TREATMENT OF LATE SYPHILIS.

Stokes²² in an excellently written paper on the treatment of late syphilis concludes as follows: The treatment of syphilis should not be parcelled out in segments, each self-sufficient and governed by its own laws. Just as we are finding that early syphilis is no longer localized, even at the earliest appearance of the primary lesion, so we shall find as the intensity of our study increases that late syphilis does not begin in the first decade, but in the first hour. Preventing the transmission of the disease in its earlier stages, and forestalling the individual tendency to complications based on the peculiarities of the strain of parasite, the host, and the method of treatment, is the whole problem of syphilis. Forestalling implies detection, so that an increasing diagnostic alertness, a development of methods for detecting the earliest and not the late signs of pathologic change in vital organs and tissues, is not mere diagnosis, but a part of effective treatment. For all our so-called prophylactic efforts, nothing will prevent the development of late complications in a certain group of patients who present the fatal combination of predisposed soil and tropic organism. It is equally true that an even smaller group of patients will master the infection for themselves, irrespective of our interference. Between these two extremes will come those whom we have radically cured, those whom we have managed to place in commensal relation to their infecting organism, those whose immunity we have broken by treatment measures whose potentialities for future harm as well as present good we do not yet understand, and those whom we have destroyed outright by treatment itself. The study of the interrelation of these groups

is one of the most complex problems of the medicine of today. Its solution will not be accomplished by a mental or physical separation of the various phases of syphilis and syphilo-therapy into air-tight compartments, each with its own technique, ideals and aims. Only that mode of approach will leave a significant impress on our future knowledge which envisages the entire disease, employs one or two methods in a large series of cases over a period of many years, records the results, and which, by lifelong observation and periodic complete re-examination, detects impending serious pathologic change, and evaluates in detail and with accuracy the response of parasite and host.

Preface.—In this, the fortieth volume of the Medical Annual, we have made some slight alteration in the arrangement of the contents which we think will be of convenience to our readers.

The articles hitherto included under Materia Medica and Therapeutics have been incorporated in the body of the work and will be found in their alphabetical order. This includes the articles on Radiotherapy, Electrotherapeutics, Non-Specific Protein Therapy, and also the therapy of the hormones, which is considered under the title 'Endocrinology.' Further reference to these methods will be found under the headings of the diseases in which they are employed.

The Introduction gives a concise summary of the principal facts and correlates them, so that the reader can readily refer to the various reports on any subject which interests him, and also quickly gather what is being done in other departments.

It has always been our aim that the Annual should not be a mere digest of the work of the year, but present it in the form of reviews by eminent physicians and surgeons, so that our readers may have the advantage of their special knowledge and experience; and also to publish original articles which will render information on subjects under discussion complete and up-to-date.

We are grateful to the entire staff of writers who have so ably cooperated in carrying out our ideal of making the Annual of material and permanent use to our readers.

To those who are familiar with the International Medical Annual the present (1922) edition is simply an old friend returning, and welcome. To those, and there are still too many, who do not know it, both its form and substance, and the fact that it has been published annually for forty years, a careful examination and the almost inevitable subsequent purchase of it will bring a welcome and long-continued sensation of surprise, pleasure and "value received."

Having quoted rather extensively both from the title page and the preface of the book, the reviewer will content himself by saying that within its 500 well printed pages it contains a

surprisingly large number of facts, admirably set down by its thirty contributors; and besides this, the opinion and judgment of the contributors upon those facts which they have collected, the book covers almost the entire field of Medicine and is neither too large nor too heavy. Would that we had a much larger number of similar textbooks.

The type is small but sharp; the plates and cuts excellent, both in outline and color; the book is admirably bound.

Transactions of the American Surgical Association. Volume the Thirty-ninth. Edited by JOHN H. JOHNSON, M.D., Recorder of the Association. Printed for the Association. For sale by William J. Dorman, Philadelphia, 1921.

This volume, of familiar form, size and color, consists of fifty papers read before the annual meeting at Toronto in January, 1921.

About 300 of its 800 pages concern fractures. A large proportion of the remaining papers relate to abdominal conditions, and include Vaughan's case of successful ligation of the abdominal aorta, the patient being alive one and one-quarter years later, working ten hours a day as a bricklayer and occasionally going on a spree to vary the monotony of life in Washington, D. C., in general, and bricklaying in particular. Vaughan gives a brief synopsis of the nineteen cases in which the abdominal aorta has been tied since Sir Astley Cooper first performed the operation on June 25, 1917.

The transactions of the American Surgical Association are always of marked interest and of great value, because they present the results and opinions of the more mature group of the best American surgeons.

SUPPOSED POISONOUS QUANTITIES OF THE GRANARY WEEVIL.

DUFFEL (*American Journal of Tropical Medicine*, Vol. II, No. 3, May, 1922) as a result of extensive experimental work with animals, concludes that the granary weevil contains no cantharidin and cannot be used as a substitute for the blister beetle, and that there is no evidence to indicate that it is responsible for cases of poisonous flour.

CHOLERA PROPRIETAS.

MAKIE and TRASLER (*Ind. Med. Gazette*, April, 1922) report results of laboratory studies of the cholera vibrio made during the British campaign in Mesopotamia. Special attention was given to the relation of the fruit season to the incidence of the disease. Experiments showed that the inside of unripened fruit, ripe or unripe, is naturally sterile. The reaction of melons and of tomatoes was found to be strongly acid and that of cucumbers mildly acid at all stages of ripening. The temperature of these fruits is lower than that of the surrounding atmosphere by 14° F. in the case of the melon, 16° F. in the case of the cucumber, and 6° F. in the case of the tomato. Temperature regulation of fruit seems to depend on the physical condition of juiciness and porosity, so that fruit maintains its temperature in obedience to the same laws which determine that of cold-blooded animals. In any case, the temperature of the fruit in hot weather is favorable to the vitality of the cholera vibrio. Despite the natural acidity of the fruit, this organism is able to live and probably to multiply on the cut surface of a melon for as long as one week. It can be recovered from melons seven days and from cucumbers and tomatoes three days after they have been inoculated. Melon pulp appears to be a particularly suitable medium for the growth of cholera germs.

The writers conclude from their studies that troops should be advised as follows:

1. Undamaged melons, cucumbers and tomatoes may be eaten with safety.
2. Ruptured or damaged fruit, especially sliced melons which have been exposed to the dust and flies of the bazar, should be strictly avoided.

[L. D. C.]

THE TREATMENT OF YAWS.

VISWALINGAM (*Ind. Med. Gazette*, May, 1922) describes yaws as it occurs in Malacca and outlines its present-day treatment. This disease, which resembles syphilis in many ways, is caused by the *Treponema pertenue* and is spread by direct or indirect contact. Inoculation takes place on an abrasion or some other skin lesion anywhere on the body, and the primary lesion is an elevated papule which later becomes granulomatous. The scab wears off, leaving an ulcer and eventually a scar. This primary sore may last as long as two years.

The secondary manifestations appear in successive crops for several years. They consist of granulomata similar to the primary lesion and may cover the entire body. Ulcers may be seen about the lips, palate and pharynx and in the nose. There is dactylitis of the fingers and toes and chronic periostitis of the lower ends of the tibia, ulna, radius, humerus and phalanges. In some cases the joints are swollen and tender. Irregular fever is not uncommon.

Tertiary skin lesions are generally confined to the soles of the feet and palms of the hands, and consist of an exfoliative dermatitis with cracks and fissures. After desquamation the skin loses its pigment, leaving a condition resembling leucoderma. Gummatous of the bones and skin sometimes ulcerate and leave deformities.

The prognosis of yaws is very good, as the disease can be arrested in all its stages. Novarsenobillon is the drug, and two or three intravenous injections are sufficient, the total adult dose being 0.9 gm. Toxic symptoms may develop after five days and should be watched for. They consist of purpuric spots, erythematous patches, epigastric distress, nausea, vertigo, and rarely collapse.

[L. D. C.]

Miscellany.

INFORMATION SERVICE OF THE ROCKEFELLER FOUNDATION.

THE International Health Board of the Rockefeller Foundation has entered into a co-operative arrangement with the Health Organization of the League of Nations whereby the Board will provide a sum not to exceed \$32,840 a year for a period of five years for the purpose of maintaining an international epidemiological intelligence service. The Board will also provide a sum not to exceed \$60,080 a year for three years to put into effect a scheme for the international exchange of public health personnel to be conducted under the auspices of the Health Organization of the League.

The Health Organization of the League of Nations was created in September, 1921. Its principal function at present is to conduct an international epidemiological information service and in general to promote international co-operation in the control of epidemic diseases. Incidentally it will advise the League in matters affecting health, and co-operate with the International Labor Organization in promoting industrial hygiene.

Since its establishment the intelligence service has kept all governments informed as to the status of epidemics of typhus, intermittent fever and cholera which have been sweeping westward from the famine-stricken regions of Russia. Negotiations among European governments looking to the adoption of sanitary conventions for the control of epidemic diseases have been initiated by the Health Organization and much progress has been made. It has also undertaken to promote the international standardization of vaccines and serums.

For the first time in the history of the world there is an agency for taking steps to control epidemics before they get out of hand. The intelligence service of the League of Nations is of vital importance to the people of all countries. It is expected that by the end of the five-year period for which funds have been provided by the International Health Board the epidemiological intelligence service will have become so efficient and valuable that the various national governments will regard it as indispensable and provide funds for its further maintenance.

The exchange of public health personnel is expected to reinforce the other activities of the Health Organization by promoting mutual acquaintance, understanding and good-will, on which effective international co-operation must be based. Interchange of health officials will be arranged not only for observation but for definite periods of service which will result in actual exchange of experience. The proposed system of exchanges will be put into effect first in Europe and may be extended as opportunity offers to other countries throughout the world.

SUBSCRIPTION TERMS: \$6.00 per year in advance, postage paid for the United States, \$7.50 per year for all foreign countries belonging to the Postal Union.

Material for early publication should be received not later than noon on Saturday. Orders for reprints must be sent to the printer with galley proof of paper. Upon written request, authors will be furnished free one hundred eight-page reprints, without covers, or the equivalent in pages in articles of greater length.

The Journal does not hold itself responsible for statements made by any contributor.

Communications should be addressed to The Boston Medical and Surgical Journal, 126 Massachusetts Ave., Boston, Mass.

VITAL STATISTICS OF MASSACHUSETTS FOR 1921.

THE report of the vital statistics of this state, as prepared by the secretary of the commonwealth and edited by the state registrar of vital statistics, has been issued. It is interesting to note that "Massachusetts was one of the first American states in which dependable registration was enforced." The earliest legislation in this state relating to this subject having been adopted by the Bay Colony in 1639. As late as 1880 only two states, Massachusetts and New Jersey, and the District of Columbia, together with a number of cities in non-registration states, were included in the registration area. The certificates of death throughout the registration area of this country are uniform. The death rates are based on a comparison of total deaths with the aggregate population. These rates vary according to the character of the population; for example, there is a higher rate among males than is found with females and where a community is largely made up of persons in those periods of life in which the death rate is normally high, the statistics vary accordingly. Other factors enter into the rates, such as the location of hospitals; for, a person sent from one locality to another for hospital treatment, who dies, swells the rate for the municipality in which the hospital is located and relieves the town from which he migrated.

Other factors, too numerous to mention in detail, also affect the comparative importance of rates in different sections and should be taken into account when studies are based on statistics.

Referring to the death rate in the registration area, the public health reports show a decline up to and including 1920, as follows:

The gross death rate from all causes in the original registration states declined from 17.2 per 1,000 in 1900 to 15.6 in 1910 and 13.9 in 1920, a decrease of 9.3 per cent. in the first decade and 10.9 per cent. in the second decade. If we take into consideration the fact that a secondary, but severe epidemic of influenza-pneumonia occurred in the early part of 1920, the indicated decline from 1910 to 1920 is less than it would have been had 1920 been a normal year. In 42 cities in the United States having a population of over 100,000, the excess death rate during the 1920 epidemic period from influenza-pneumonia alone was about 1.13 per 1,000. If the same excess may be presumed to have occurred in these original registration states, the death rate in 1920 would have been approximately 12.8 per 1,000, and the decline from 1910 would have been about 18 per cent.

The Massachusetts report shows a similar improvement, but the 1921 report for the whole area is not available for comparison with the 1921 report of Massachusetts.

Number of Deaths and Death Rates in this State: There was a decrease in the mortality of 1921 as compared with that of 1920, the number of deaths occurring during the calendar year 1921 being 47,780, a decrease, as compared with 1920, of 5,852. Based on the estimated population of 1921 of 3,885,836, these deaths correspond to a rate of 12.3 per 1,000 population, as compared with 13.9 in 1920. This rate for 1921 is the lowest ever recorded in Massachusetts.

During the last two ten-year periods the death rate of the commonwealth has fallen from 18.2 in 1900 and 16.2 in 1910, to 13.9 in 1920.

Of the 47,780 deaths in 1921, 7,005, or 14.7 per cent., were of infants under one year of age. It is a singular fact that even with infants the mortality is higher among males than is the case with females, the per cent. of male infant deaths being 58. No explanation has been given for this larger mortality in this class.

The winter months record the higher mortalities, March, January and February presenting the largest figures in the order named.

The infant mortality in 1921 was 75.9 per 1,000 live births, which is the lowest rate ever recorded in this state.

The highest proportion of deaths occurred in the early period of life, for 39.5 per cent. of all deaths under one year of age occurred in the first week, the first day showing a mortality of 19.2 per cent., and 79.9 per cent. of the infant deaths occurred in the first half year.

The causes of early death are prematurity, congenital debility, malformations or injuries

received at birth. These account for 77.5 per cent. of those infants that died less than one week after birth.

Of the 47,780 deaths, pneumonia was the cause of 4,200; heart disease, 7,197; tuberculosis, 3,867; apoplexy, 4,262; malignant tumors, 4,645; Bright's disease, 3,157; diphtheria and croup, 607. Typhoid fever fell to 119.

The number of deaths investigated by medical examiners is 6,368. Post mortem examinations were conducted in 621 of these cases.

Under classification of the puerperal state there were 580 deaths; of these there were 48 due to accidents of pregnancy, 20 to abortion, 11 to ectopic gestation; others under this title, 17; puerperal hemorrhage, 74; other accidents of labor, 92 Cesarean section, 35; other operations and instrumental deliveries, 18; unclassified under operations, 39; puerperal septicaemia, 178; puerperal phlegmasia alba dolens, embolus and sudden deaths, 56; puerperal albuminuria and convulsions, 131; and one following childbirth not defined.

In explanation of the sources of error in mortality statistics, it is claimed in the report that inaccuracy on the part of physicians is the chief element. In all probability if any considerable number of physicians were given an opportunity to express opinions, some criticism of the requirements outlined on the blanks would be submitted. The questions on the blanks are to some extent like those sometimes propounded by a lawyer to a witness, for it is not always possible for a physician to answer the questions and have the satisfaction of feeling that he has given all the information which he would like to impart. The suggestion also appears in this report that a physician may, at the request of the family of the decedent, deliberately withhold a statement of the true cause of death. If this is so, and it probably is believed to be so, or it would not appear in a public document, some person, official, or department, is blameworthy in allowing this source of error to be continued. Vital statistics are of vital importance and should be as nearly free from error as it is possible for human agents to make them so. Many changes have taken place in medical nomenclature and medical knowledge is being constantly revised and a return could be devised which would enable students of statistics to acquire accurate information. Under the present system the possibility of faulty interpretation exists, to some extent.

SCHOOL HEALTH SUPERVISION.

In the *American Journal of Public Health* for June, 1922, Dr. S. Josephine Baker presents a history of school medical inspection. Boston inaugurated the first system of this sort in 1894, which was designed to limit the spread of disease. This consisted of daily visits to schools

by physicians for the purpose of inspecting children suspected by the teacher of being infected by a contagious disease. Philadelphia adopted this custom in 1896 and New York a year later. In 1905 New York City adopted a program which included physical examination of school children for the purpose of discovering physical defects. This type of school work is required in five states and is permitted in 29. Some other states have school physicians that carry on through diplomatic means more or less work of this kind. These methods led up to health control of school children, including teaching of health habits, sometimes through officials and in some cases by voluntary organizations. The extent of physical examinations was determined in many instances by the amount of money appropriated, sometimes being repeated during school life, but few communities have ever appropriated enough money to make a reasonable number of examinations of all the pupils. Many authorities feel that every child should be carefully and thoroughly examined every year, but even where this requirement exists the examinations are seldom complete and are apt to consist of inspection rather than examination, for great expense is involved in general careful examination, so that for some time to come the real task is to get the best possible results within the appropriations.

Dr. Baker shows that reports indicate quite universally that 35 per cent. of the children of school age have one or more physical defects, such as malnutrition, defects of hearing, lung disease, hypertrophied tonsils, adenoid growths, and defective vision; and if defective teeth be added the percentage would be much higher, for it is found that among certain groups even 65 per cent. have defective teeth. Practically every child needs dental care during school life, so that oral hygiene should be an essential part of health work among this group.

It is obvious that in order to correct physical defects the detection should be early.

A study of 356,292 children of the city of New York shows that school life does not have a bad effect on defective hearing and pulmonary and cardiac diseases, but, on the other hand, nervous diseases and defective eyesight seem to become more frequent during school life.

The conclusions presented by Dr. Baker are as follows:

1. The most important physical examination to be made in the school life of the child is the one occurring at the time the child enters school for the first time.

2. In order to make the work of health supervision of school children effective, a complete physical examination of each child should be made before the 8-to-10-year period. If this can be done with 100 per cent. efficiency, combined with follow up that is 100 per cent. effective and 100 per cent. of treatments obtained, it should not be necessary to make regular

physical examinations after the 8-to-10-year period, reliance being placed after that time upon the routine inspection of the children in the classroom. This routine inspection will permit the nurse, doctor or teacher to pick out the cases of physical defects that have been in any way overlooked during routine physical examinations or which have originated after the 8-to-10-year period.

3. An annual test for defective vision is desirable.

4. Unless the amount of money appropriated for school medical inspection is large enough to allow a complete and thorough physical examination each school year, the officials in charge of such work are not justified in spending any money in having physical examinations made after the 8-to-10-year period unless the full health needs of the children below that age period have been met.

5. A logical deduction that might be drawn from this study is that great emphasis should be placed hereafter upon the pre-school age period as the time when physical defects should be prevented or corrected.

6. To sum up the matter, this study would seem to show that the expenditure of time and money to make annual physical examinations of school children is not warranted and seems to be unnecessary. Analysis of the age and sex incidence of physical defects in this study shows that proper and adequate physical examinations made in the early life of the school child—that is, before the 8-to-10-year period—are essential, and if these are properly followed up and suitable treatment obtained, the appropriations for this work will be spent in the most economical way, the child's health will be more thoroughly protected, and future disease and the sequelae of physical defects be more adequately guarded against than by any of the present methods of school health supervision.

These conclusions will be a source of comfort to those persons who feel very strongly that physical examinations of children should be conducted upon entrance to the public schools. This plan is, however, a bone of contention, for certain of our people feel that the personal rights of the child should not be invaded through physical exposure, and by others that extension of state supervision of the health of children may lead to the development of plans covering some delicate problems of life and morals.

Although more attention to defectives and instruction in health matters will probably never lead the majority to favor attention to sex hygiene, that is so much feared by many, that progress must of necessity be slow until greater confidence in the wisdom of our school and health departments shall have been developed. It may be possible to interest large numbers of parents in the physical examination of children at regular intervals by the family phy-

sician. This course would be productive of good results and in time would bring about better average health among adults. It may be utopian to expect parents to provide for that kind of investigation for children which is not generally sought by adults for their own safety. By constantly dwelling on the importance of the scientific study of every individual a sufficient response may follow that will lead to better average conditions.

THE STATE ASSOCIATION OF BOARDS OF HEALTH.

THE summer meeting of this organization was held at the Atlantic House, Nantasket, July 27. The meeting was presided over by Captain William J. Young, agent of the Springfield Board of Health. Three new members were elected. Dr. Champion of the State Department of Health outlined the program for maternal and infant welfare work. The plans for the future are for a continuation and amplification of the work which has been carried on for several years. There seems to be some misunderstanding relating to the nature and scope of the efforts made by the State Department, so that a recital of facts and purposes is pertinent at this time.

The Department has never been favorable to the benefit laws and practices of Italy, France, England and Germany; for the present policy of this state is not based on the insurance benefit plan but rather the dissemination of information and advice. In speaking of records relating to maternal and infant mortality the speaker spoke of the accuracy of the New Zealand records and added that Massachusetts' records are given high rank in Washington.

A review of attempts at legislation was given, and the opinion expressed that we do not need poor relief legislation relating to this class of patients in this state. He paid high tribute to Dr. Alfred Worcester and his committee and felt that the efforts of this group of public servants were not appreciated, because the time given to the commission was so short and the problem so complicated that service involved great concentration and sacrifice of time and strength. He did not feel that the Sheppard-Towner Act is the best solution of the problems involved.

In order to carry on the work Massachusetts has appropriated \$15,000 for four months' work and \$30,000 more for the remainder of a year, to be expended by the Division of Hygiene in the State Department of Health. Speaking of other states, reference was made to Maine, which has appropriated \$5000 for this work, but Rhode Island and Illinois have not acted thus far. New York has appropriated a very large amount, but has not seen fit to adopt the

Sheppard-Towner Act. The prosecution of this work means that in order to secure effective action local authorities must cooperate. Reference was made to the claim that maternal mortality has increased 70 per cent. in the last 16 years, and the need of better vital statistics was emphasized, for reports of deaths do not always convey the information sought.

The question was raised concerning the reasons for higher mortality rates, and certain facts relating to infant mortality were especially emphasized, for although there is a general claim that infant mortality is decreasing in Massachusetts, the mortality of early infant life remains the same and there has been no appreciable change in the number of stillbirths, for they vary only a fraction of one per cent. from year to year. The great outstanding factor relating to infant mortality seems to be ignorance of hygiene, and it is hoped that efforts which are to be made will reduce the mortality of infants, especially of those under one month. Great hope was expressed that the money secured through taxation would show satisfactory results soon.

Dr. Charles P. Sylvester, of the Hull Board of Health, distributed a pamphlet relating to the control of the mosquito nuisance.

There were 38 representatives of different boards present, but the attendance was not as large as on some previous occasions. It was felt that the meeting was instructive and stimulating.

THE EFFICIENCY OF ARSPHENAMINE AND NEOARSPHENAMINE.

ALTHOUGH arspenamine and neoarsphenamine have been in use for about twelve years, doubt has been expressed as to the relative efficiency of these remedies. Opinions of clinicians have been published, but have not been supported by scientific experiments which are conclusive. The difficulties incident to a comparison of the parasitocidal power of these agents, when used on human subjects, are very great, but the importance of the question involved has led Carl Voegtlin, Professor of Pharmacology, and D. W. Miller, Scientific Assistant, U. S. Public Health Service, to make an experimental study of the value of these two compounds. They used rats infected with the *trypanosoma equiperdum*. This is the parasite which causes the so-called horse syphilis and which produces a chronic disease with a definite pathology. Albino rats quickly succumb to infections by this parasite, the multiplication of the parasites proceeding almost according to a fixed rate, as shown by a double number in approximately seven hours. A given dose of the drug may be depended upon to kill a certain number of parasites. The tests were applied to 13 lots of arspenamine and 15 lots of neoars-

phenamine. The results showed that the parasitocidal power of arspenamine of different manufacture is remarkably constant, but that there was a great variation in the results obtained by the use of neoarsphenamine.

In the report reference is made to the work of Dale and White of the National Institute of Medical Research in London, in which a record is given of the use of mice, which is confirmatory of the conclusions which are formulated by Voegtlin and Miller, as follows:

1. The results obtained in this investigation confirm previous data from this laboratory to the effect that arspenamine of different manufacture is fairly uniform in parasitocidal power, whereas neoarsphenamine shows great variations.

2. The toxicity of the average commercial arspenamine and neoarsphenamine manufactured at the present time is considerably lower than that of preparations found on the market two years ago.

The full account of the technic employed may be found in The Public Health Reports under date of July 7, 1922.

RURAL HEALTH SERVICE.

THE Rural Sanitation Office of the United States Public Health Service reports that there are 203 counties throughout the United States that have a local health service under the administration of whole-time county or district health officers. Massachusetts is listed as having only one and that is in the Cape Cod District. The rural population of Massachusetts is recorded as 202,108, of which 11,558 have this service. The further statement is made that only 5.71 per cent. of our people are thus served. Like many statistics, these figures are to some extent misleading, for the casual reader, unfamiliar with conditions in this state, would not know that the State Department of Health, through its seven district health officers, pays attention to rural health problems. It may be that better results would be secured if all counties would provide a full-time health officer acting in association with our district health officers, but the present system is certainly efficient to a large degree.

CHIROPRACTORS ADVERTISING IN CHURCHES.

Two Methodist churches, one in Elkhart and one in Fort Wayne, Indiana, have given the chiropractors the use of their edifices for propaganda purposes. This is a clever move. Any quack could appeal to an audience of medically uneducated persons and make fools of a certain proportion. Claims of successful treatment

of diseases have enriched pretenders from the earliest times. The ability to analyze and apply sound reasoning to problems of daily life is denied to many. The associations of church life carry a certain endorsement of views presented to some minds. This is an illustration of the use of good material for unholy purposes. In the East we expect the chiropractors to use all possible means for the purpose of securing endorsement, but we cannot conceive of the possibility of lending churches to advancing the interests of the cults in this state. When the campaign for legalizing the chiropractors is inaugurated in this state we trust that average intelligence will not permit desecration of holy places.

NEWS ITEMS.

THE EXECUTORS OF THE ESTATE OF DR. EDWARD H. NICHOLS have arranged with Dr. Thomas K. Richards, who has been for the last three years Dr. Nichols' associate and assistant, to continue the practice of Dr. Nichols at 294 Marlboro Street.

INFANTILE PARALYSIS.—Thirty-five cases have been reported in Rhode Island, with six deaths. The State Board of Health is actively at work to prevent further spread of the disease.

WEEK'S DEATH RATE IN BOSTON.—During the week ending July 29, 1922, the number of deaths reported was 152, against 203 last year, with a rate of 10.38. There were 23 deaths under one year of age, against 29 last year.

The number of cases of principal reportable diseases were: Diphtheria, 32; scarlet fever, 17; measles, 38; whooping cough, 31; typhoid fever, 4; tuberculosis, 44. Included in the above were the following cases of non-residents: Diphtheria, 2; scarlet fever, 2; tuberculosis, 8.

Total deaths from these diseases were: Scarlet fever, 2; typhoid fever, 1; tuberculosis, 12. Included in the above were the following cases of non-residents: Scarlet fever, 1; typhoid fever, 1.

THE WINTHROP HOSPITAL.—The successful completion of the drive for a total of \$35,000 for the Winthrop Community Hospital was celebrated by a dinner and reception at the Cliff House, Winthrop Highlands, July 31 last. This money will be used in purchasing the Dr. Metcalf hospital and providing for its equipment.

DEATH IN SERVICE.—Laboratory Assistant William E. Gettinger, United States Public Health Service, died at Hamilton, Mont., June 30, 1922, of Rocky Mountain spotted fever, contracted while in line of duty and engaged in laboratory work in connection with the investi-

gation of that disease, known to be one of the most fatal of diseases when contracted in the laboratory.

FORTY-FIFTH ANNUAL REPORT OF THE ADAMS NERVE ASYLUM.—The managers of this institution report a successful year. The Asylum, which was founded for the benefit of indigent, debilitated, nervous people who are not insane, has rendered service this year to 195 patients, of whom 51 were treated free. The daily average number of patients was 32. It is encouraging to note that the cost of running the Asylum was about \$6,000 less than previous years.

CHANGE OF OFFICE.—Dr. Joe Vincent Meigs has removed his office to 286 Marlborough Street, Boston.

SUSPENSION OF DR. JOSEPH LEVEK.—The Board of Registration in Medicine conducted hearings August 2, 1922, for the consideration of complaints against four physicians in which gross unprofessional conduct was alleged. Three of the cases were brought to the attention of the Board by Federal prohibition agents and related to alleged irregularities in connection with prescriptions for alcoholic liquors. The Board dismissed one case and postponed action in two others of this class.

The most important hearing was held because of complaints filed by physicians of Lawrence, who felt that the defendant, Dr. Joseph Levek, of 32 Lawrence Street, Lawrence, Mass., an associate on a hospital staff, had improperly treated a person. The Board suspended the registration of Dr. Levek for one year. Complaint has been entered in court at Lawrence and Dr. Levek is held in \$3,000 bonds for further court proceedings August 15, 1922. The probability of a trial makes further reference to this case at this time improper.

The Massachusetts Medical Society.

MEMBERSHIP CHANGES FOR THE MONTH OF JULY, 1922.

OFFICIAL LIST (6TH).

Compiled by the Secretary.

ALPHABETICAL LIST.

Atchison, Charles M., New Bedford, now 459 Mill St.
 Baker, Leonard Allen, Middleboro, office now Sullivan Building.
 Begg, Alexander S., from Jamaica Plain to West Roxbury, office Boston, 80 East Concord St.
 Bessey, Earle E., Waban (Newton), now 1690 Beacon St.
 Blackway, Charles E., Fall River, now 132 Franklin St.
 1905-1922.—Brennan, Thomas Joseph, Little Compton, R. I., office Fall River, 151 Rock St.

- Brigham, F. Gorham, from Suffolk to Norfolk, Brookline, office Boston, 35 Bay State Road.
- Brittingham, Harold N., from Roxbury to Cleveland, Ohio, 2753 Euclid Heights Boulevard.
- Burnett, Joseph H., now Boston, 483 Beacon St.
- Brown, Lloyd T., from Suffolk to Norfolk, Milton, office Boston, 372 Marlborough St.
- Carr, Earl B., from Melrose to Montrose, Minn.
- Chromquest, Alfred P., from West Roxbury to New York, the Bronx, U. S. Vets. Hosp. No. 81.
- Cobb, Farrar, from Suffolk to Norfolk, Brookline, office Boston, 419 Boylston St.
- Cody, Peter White, died at Lawrence, July 15, 1922, aged 64.
- Cunningham, Allan R., Boston, now 483 Beacon St.
- Cunningham, John Henry, from Suffolk to Norfolk, Brookline, office Boston, 46 Gloucester St.
- Curtis, Harlan F., from McCook, Nebraska, to Charles City, Iowa.
- Cusick, Laurence Francis, Nahant, office now Boston, 320 Marlborough St.
- Cushing, Arthur A., Brookline, now 100 Sewall Ave.
- Cutter, Irving Taylor, from Winchester to San Antonio, Texas, Moore Building.
- Darling, Charles B., from Norfolk to Middlesex South, Roxbury to Waban, office Boston 483 Beacon St.
- Day, Hilbert P., from Suffolk to Middlesex South, Cambridge, office Boston, 45 Bay State Road.
- De Wolf, Charles W., Wakefield, office Boston, now 358 Commonwealth Ave.
- Dix, George A., Worcester, now 6 Ashland St.
- Emery, Edward S., Jr., Brookline, office Roxbury, Peter Bent Brigham Hospital.
- Favaloro, John, from Middlesex North (Lowell) to Essex South, Lynn, 275 Summer St.
- Ferrin, William W., Haverhill, now 77 Emerson St.
- Fiske, Eustice Lyman, from Fitchburg (Worcester North) to Croton-on-Hudson, N. Y.
- Fitz, Reginald, from Mayo Clinic, Rochester, Minn., to Roxbury, Peter Bent Brigham Hospital.
- Foley, John Arthur, from Suffolk to Norfolk, Dorchester, office Boston, 514 Commonwealth Ave.
- Forsley, Thomas, Jr., Lowell, now 308 Merrimack St.
- Gilpatrick, Roy Hawkes, from Suffolk to Middlesex South, Brighton, office Boston, 19 Bay State Road.
- Goethals, Thomas K., from Suffolk to Norfolk, Brookline, office Boston, 443 Beacon St.
- Harris, Paul L., from Lowell to Ellis Island, N. Y., Marine Hosp. No. 43.
- Haywood, Ralph W., Salem, now 24 1-2 Winter St.
- Hooper, George Henry, Boston, now 722 Commonwealth Ave.
- Horr, Albert W., from Suffolk to Middlesex South, Malden, office Boston, 419 Boylston St.
- Hubbard, Eliot, Jr., from Suffolk to Norfolk, Roxbury, office Boston, 74 Bay State Road.
- Iovanna, Nicholas, from Boston to Revere, office Boston, 256 Hanover St.
- Keenan, George F., Boston, now 207 Bay State Road.
- Kelley, Henry Joseph, Beverly, now 25 Broadway.
- Kershaw, George H., Fall River, now 163 Stafford Road.
- Kleinert, Margaret Noyes, from Suffolk to Norfolk, Jamaica Plain, office Boston, 82 Commonwealth Ave.
- Lewis, Frank Edward, Nantucket, now 2 Chestnut St.
- Libby, Edward N., from Roxbury to Jamaica Plain, office Boston, 638 Beacon St.
- Liuenthal, Harry, from Roxbury to Brookline, office Boston, 45 Bay State Road.
- Livingston, William K., from Boston to Eugene, Oregon, Univ. of Ore. Health Service.
- Lurie, Moses Hyman, from Suffolk to Norfolk, Roxbury, office Boston, 483 Beacon St.
- Lyman, Henry, Brookline, office Roxbury, Huntington Memorial Hospital.
- Lyons, Joseph Benedict, died at Charlestown, July 18, 1922, aged 51.
- McCarthy, Eugene A., Fall River, now 422 North Main St.
- Macdonald, William Joseph, Boston, now 9 Massachusetts Ave.
- McKittrick, Leland S., from Suffolk to Norfolk, Brookline, office Boston, 520 Commonwealth Ave.
- McLellan, William Edwin, from Lynn to Buffalo, N. Y., U. S. P. H. S. Marine Hosp.
- Mandell, Augustus H., New Bedford, office now 101 School St.
- Mason, William, Fall River, now 151 Rock St.
- Mathewson, Frank W., New Bedford, office now 98 Spring St.
- Maynard, Herbert E., from Suffolk to Middlesex East, Winchester, office Boston, 178 Commonwealth Ave.
- Mitchell, William, from Needham Highlands to Needham Heights, 511 Highland Ave.
- Milward, Francis W., Cleveland, Ohio, now 11636 Detroit Ave.
- Morrison, William Reid, from Suffolk to Middlesex South, Brighton, office Boston, 527 Beacon St.
- Mysel, Philip, from Suffolk to Norfolk, Roxbury, office Boston, 259 Hanover St.
- Nowell, Howard W., from Suffolk to Norfolk, Brookline, office Boston, 416 Marlborough St.
- Nute, Albert James, from Suffolk to Norfolk, Jamaica Plain, office East Boston, U. S. Immigration Station, Station.
- O'Brien, John Francis, Taunton, now 632 Somerset Ave.
- Odeneal, Thomas F., Beverly, now 37 Abbott St.
- Ormsby, Edward B., from Suffolk to Norfolk, Milton, office Boston, 350 Commonwealth Ave.
- Palmer, George Monroe, died at Lynn, July 21, 1922, aged 59.
- Papen, George William, from Suffolk to Middlesex South, Allston, office Boston, 520 Commonwealth Ave.
- Parker, Frederick D., Brookline, now 37 Claflin Road.
- Parker, Willard S., from Suffolk to Middlesex South, Watertown, office Boston, 483 Beacon St.
- Phaneuf, Louis E., from Suffolk to Norfolk, Brookline, office Boston 514 Commonwealth Ave.
- Pierce, Appleton Howe, from (Worcester North) Leominster to (Norfolk) West Roxbury, U. S. Vets. Hosp. No. 44.
- Provost, Raoul G., New Bedford, now 119 Hillman St.
- Raeder, Oscar J., from Neuilly-sur-Seine, France, to Roxbury, 74 Fenwood Road.
- Rice, Robert, died at Haverhill July 9, 1922, aged 52.
- Richards, Thomas K., from Suffolk to Middlesex South, Cambridge, office Boston, 294 Marlborough St.
- Richardson, Oscar, from Suffolk to Norfolk, Roxbury, office Boston, Mass. General Hospital.
- Risley, John N., New Bedford, now 271 Union St.
- Robbins, Elmer E., Jr., New Bedford, now 449 Pleasant St.
- Root, Howard Frank, from Roxbury to Brookline, 10 Welham St.
- Sawyer, Howard P., Fall River, office now 122 Purchase St.
- Seaver, Edwin P., Jr., New Bedford, now 7 North Sixth St.
- Sedzley, Frank Robert, from Staten Island, N. Y., to St. Paul, Minn., U. S. Vets. Hosp. No. 65.
- Segall, Samuel K., New Bedford, now 179 William St.
- Senecal, Raymond E., New Bedford, now 310 Sawyer St.
- Shedden, William M., West Newton, office Boston, 57 Marlborough St.

Simpson, Charles Moffett, Boston, now 98 Queensberry St.
 Solomon, Harry C., Jamaica Plain, office now 270 Commonwealth Ave.
 Sylvester, Charles Porter, Boston, now 899 Beacon St.
 Smith, Laurence Weld, from Brookline to Manila, P. I., University of the Philippines.
 Stein, Louis C., Boston, now 333 Commonwealth Ave.
 Stone, Moses J., Dorchester, office now State Infirmary, Tewksbury.
 Ullian, Louis Joseph, from Suffolk to Norfolk, Roxbury, office Boston, 68 Bay State Road.
 Vershow, Nathan, Hartford, Conn., now 28 Sisson Ave.
 Webber, Isaac Mervyn, from Worcester to South China, Maine, P. O. Weeks Mills, Me.
 Wright, James Homer, from Suffolk to Middlesex South, Newton Center, office Boston, Mass., Gen'l Hospital.

ADDRESSES UNKNOWN.

Azadian, David George.
 Kelley, Robert Edward Stack.
 Lawlor, John Charles.
 McClintock, Elsie.
 McConnell, David James.
 O'Donnell, George Thomas.
 Seibels, Robert Emmett.
 Whitcomb, Clarence Adelbert.

Changes of address should be sent to the Secretary, Dr. Walter L. Burrage, 42 Eliot Street, Jamaica Plain 30.

Correspondence.

WALTER REED GENERAL HOSPITAL OFFERS A COURSE IN PHYSIOTHERAPY

Mr. Editor:

A course in physiotherapy, covering a period of one year will be offered at Walter Reed General Hospital, Washington, D. C., beginning Oct. 2, 1922. Credit will be given for previous training in Physical Education, Nursing, Physiology and Anatomy, so that the course may be completed in six months or even less. The schedule of subjects included all branches of physiotherapy, and, in addition, lectures in general hospital subjects.

Accepted candidates will be listed as student aides, and will be furnished quarters, rations, laundering of uniforms, and, in addition, \$15 per month. No tuition fees are required.

Graduates will be eligible for positions in the Physiotherapy Department in army hospitals, and are expected to serve one year. Graduate aides in army hospitals are provided quarters, rations, laundering of uniforms, and are paid a base salary of \$60 per month, plus a Congressional bonus of \$20 per month.

Application blanks will be mailed on request.

K. F. KESMIDELL,
 Major, Med. Corps, U. S. Army,
 Acting Director of Physiotherapy.

RECENT DEATHS

DR. GEORGE HENRY TALBOT, a member of The Massachusetts Homeopathic Medical Society, died at his home in Newtonville July 28, 1922, at the age of sixty-three. He was born in Norwood, graduated at Boston University School of Medicine in 1882 and settled in practice in Bellows Falls, Vt. There he met his wife, Jessie E. Talbot. Moving to Newtonville in 1888, he became a member of the staff of the Newton hospital. During the war he took the place of a younger practitioner who went to the front

during that time Dr. and Mrs. Talbot assisted the Red Cross, turning over their house as a headquarters for the local chapter. In addition to his wife he is survived by two daughters.

DR. FREDERICK AUGUSTUS DAVIS, a member of the Massachusetts Homeopathic Medical Society and of the American Institute of Homeopathy, died at his home in Boston July 29, 1922, after an illness of four weeks. He was born in Ellsworth, Me., March 24, 1863, and graduated from the Hahnemann Medical College and Hospital, Philadelphia, in 1884, settling in practice in Belfast, Me. After moving to Boston in 1889 he was connected with the Homeopathic Dispensary and with the Boston University School of Medicine, where he was a lecturer on diseases of the stomach. At one time Dr. Davis was president of the Boston Surgical and Gynecological Society. He was a Mason, an Odd Fellow, and a Knights Templar. His wife, who was Susie Blaisdell Goodell of Boston, and one son survive him.

MEDICAL MEETINGS

The JOURNAL would like to publish a schedule of all medical meetings in this state and others of general interest.

A previous announcement of the plan has not led secretaries of societies to send in data to any great extent. It has happened quite often in the past that notices to members of societies have been lost or forgotten and subsequent reference to a meeting has made a member regret that lapse of memory led to non-attendance. It has also happened that two meetings have been scheduled for a given date and the inability to attend both has been disappointing. A publication of dates may lead to the selection of days which may be free.

PRENDERGAST PREVENTORIUM

The executive committee of the Boston Tuberculosis Association has issued invitations for visits to the Preventorium August 15 from 4 to 7 p. m. Tea will be served and visitors are asked to bring a lunch. The Preventorium is on Harvard and Ashland streets, Mattapan. Take Elevated to Forest Hills and change to Milton car.

BOOKS AND PAMPHLETS RECEIVED

MERCK'S SPECIALTIES. A list of therapeutic agents with notes as to special usage, dosage, etc. (Among the newer drugs listed in this pamphlet are "Encupin," "Vuzin," and other compounds related to quinine which have been attracting some attention in Europe recently.) Copies may be obtained free of charge by addressing Merck & Co., 45 Park Place, New York City.

REPORTED TO MASSACHUSETTS DEPARTMENT OF PUBLIC HEALTH.

Week Ending July 22, 1922.

THE DIAGNOSIS OF DISEASES OF THE URINARY TRACT.*

(WITH ESPECIAL REFERENCE TO THE COMPARATIVE VALUE OF THE VARIOUS DIAGNOSTIC DATA).

By WM. C. QUINBY, M.D., BOSTON.

[From the Urological Clinic of the Peter Bent Brigham Hospital.]

Is no branch of major surgery are the methods of arriving at an accurate pre-operative diagnosis so numerous and so reliable in their detailed findings as are those which are applied to diseases of the urinary tract.

During the past fifteen to twenty years much progress has been made, so that the older teachings in many respects have had to be modified. For instance, it is well recognized today that the classical description of renal colic, the so-called Dietl's crisis, of pain sharp and cutting, referred downward from the kidney region along the course of the ureter to either the testicle or vulva, may hold true of one patient, while in another, bearing identical lesions, this type of pain may be absent or greatly modified. Or, again, in regard to the conclusions to be drawn from the examination of the urinary sediment, much stress used to be placed on the finding of

pus in clumps, or of caudate cells, or of the so-called compound-granule cells, as characteristic of different portions of the urinary passages. Now we know that such details as these are quite valueless, it having become possible to localize diseases by other and much more accurate methods. Though the observation of patients regarding their own symptoms is well known to be often inaccurate, nevertheless, a careful history and general physical examination are still of as much importance as ever.

Concerning the analysis of the urine, the absence of albumen or its presence in varying amounts is of less significance by far than is the amount of urine excreted during twenty-four hours and the combined function of the kidneys as measured by the phenolsulphonephthalein test. Formed elements in the sediment, such as pus, blood or casts, are of much more significance than are various types of fixed tissue cells or the occasional finding of crystals. Frequently the data from bacteriological investigation of the urine are of importance, especially as regards the presence or absence of tuberculosis.

Excluding, then, those findings in the urine which accompany the various nephropathies commonly classed as Bright's disease, the most important elements from the point of view of the urologist are pus and blood occurring either singly or combined. Either of these is an important finding, and its source must be carefully sought and identified by the usual diagnostic

*Presented before the Boston Surgical Society, April 3, 1922.

procedures. Indeed, too much stress cannot be laid on the fact that it is the duty of all physicians today to see to it that in every case of hematuria or pyuria, the source of such is accurately determined, at the earliest possible date following its appearance. Of no less importance is it, however, to recognize the fact that there exists a variety of ailments of the urinary tract in which the urine may be found to be absolutely normal. Therefore, if the urine contains positive evidence of disease this is important, but negative evidence by no means excludes.

Following the history, the physical examination, including blood pressure and renal function test, and the urinalysis, we come to the data obtained by the radiograph, and this leads to a discussion of the relative values and proper interpretation of such shadows as may be found in the x-ray plate. Since this is in its ultimate analysis only a graphic record of varying degrees of density, it frequently happens that shadows so found need confirmation before an absolute opinion regarding their significance can be expressed. If the suspicious shadow involves the bladder it can be confirmed by ocular examination of this organ through the cystoscope, while if it concerns the ureter or kidney the passage of leaded catheters into the ureters or the injection of a solution opaque to the x-ray into the kidney pelvis will be necessary. In other words, the finding in an x-ray plate of a shadow which is consistent with that of a ureteral stone, let us say, is not today sufficient evidence on which to advise and perform an operation for the removal of such stone until absolute confirmation of the shadow by accessory methods has been accomplished.

As regards the data to be derived from a simple x-ray examination of the urinary tract, then, we may say that they are of great importance in our diagnosis, but only when confirmed. When such data are derived from an examination which has been made after the renal pelvis and ureter have been outlined by opaque substances,—in other words, when accessory diagnostic methods have been added to the x-ray,—then the value of such data is paramount and incontrovertible.

On all data obtained by the use of the endoscope and cystoscope we may place definite reliance, limited only by the degree of experience of the observer. Instances of infection in urethra or bladder, as well as stone, diverticulum, or foreign body in the bladder, are easily recognized. In the differentiation between benign and malignant growths in the bladder cystoscopic data may be at times inconclusive, but if we remember that all the common bladder neoplasms are at least potentially malignant, and if we act accordingly, no great error will arise from this cause.

This is not always the case with those findings which result from attempts to investigate the

product of each kidney separately by the use of the ureteral catheter, though as a rule complete reliance can be placed on them. The commonest difficulty arises from the occasional inhibition of renal function caused by the passage of the catheter. This is not nearly so apt to occur if the kidneys are in a state of active diuresis at the time of the observation. To obviate this type of temporary anuria, therefore, the patient should have taken several glasses of water within the hour immediately preceding the cystoscopic investigation. A second minor difficulty occurs occasionally in those instances in which the microscopical examination of the urine collected through the ureteral catheter shows a few blood cells. These may be due to renal disease or they may have been caused by the trauma incident to the passage of the catheter. It is impossible to tell which is the case, so that their presence must be ignored; or if the matter seems important, a second observation should be made as a check on the first. With the exception of such minor considerations as these, the data obtained by the use of the ureteral catheter are reliable and of great value.

Lastly, those data which are obtainable by the injection of solutions opaque to the x-ray, in order to outline the urinary passages, just as the intestinal tract is outlined by the ingestion of barium or bismuth, are of the utmost importance and may frequently even be the only ones on which an accurate and proper diagnosis can be based. The pyelogram or ureteropyelogram is subject to no errors that I am familiar with except always, of course, those of misinterpretation, and this is very rare.

In our present stage of diagnostic knowledge as it concerns the urinary tract it is fair, I think, to suggest the following as working rules or postulates.

1. Do not rush to the use of such modern diagnostic aids as the cystoscope before having taken a detailed history of the patient and having made a thorough general physical examination.
2. Examine the urine, especially for microscopic amounts of pus or blood, but do not feel that if the urine is normal this fact excludes the possibility of disease in the urinary tract.
3. Look with the eye of a skeptic on all shadows in the plain x-ray plate which seem to mean lithiasis within the urinary passages until such shadows have been proven by further measures to be in fact within these passages.
4. The accurate and early determination of the exact source of pus or blood in the urine is imperative. This can only be satisfactorily accomplished by the use of the cystoscope and ureteral catheter.
5. The data to be learned by the pyelogram are frequently of the greatest importance. This procedure should therefore be carried out frequently, often as an aid in the elucidation of

the source of abdominal pain whatever its location.

To make some of the above points clear a consideration of the following cases will be of interest, especially as regards the importance of data obtained by means of the x-ray:

Bladder. A. X-RAY SHOWS SHADOWS.

(Raising question as to whether these are in the bladder or urinary passages.)

nancy. Cystoscopic examination of the bladder immediately showed that this organ was entirely free from stones and that the only pathological condition present of any consequence was cancer of the prostate. Thus the shadows in the x-ray plate were shown to be either phleboliths or calcified lymph nodes.

B. X-RAY SHOWS NO SHADOWS.

CASE 2. A man forty-nine years of age com-

FIG. 1.—CASE 1.

CASE 1. A man seventy years old complained of the general symptoms of an obstruction at the neck of the bladder caused by the prostate. X-ray examination of the bladder had been made, in which numerous small shadows were found. Rectal examination had shown a condition of the prostate suggesting malignancy, and the patient had been given the diagnosis of cancer of the prostate, together with stones in the bladder, in spite of the fact that the urine was normal. Considered critically, of course, this might be true; or it was conceivable that the whole condition was due to prostatic calculi with accompanying induration of the prostate, a condition sometimes closely simulating malignancy.

Plain x-ray plate of the bladder showed nothing abnormal, but on filling the bladder with a shadow-casting solution the presence of a diverticulum immediately became evident.

CASE 3. A man forty-five years old complaining of hematuria, together with undue frequency of urination, was examined by the x-ray and no abnormalities seen, but on filling the bladder, as in the previous case, we immediately found extensive defects in the bladder outline caused by the presence of multiple neoplastic growths.

Ureter. A. X-RAY SHOWS SHADOWS.

FIG. 2.—Case 2.

FIG. 5.—Case 4.

FIG. 4.—Case 3.

FIG. 7.—Case 5, ILLINOIS. The dark area in the line of dilatation beyond the catheter tip marks the presence of the stone. Note the dilatation of the ureter above the level of obstruction.

FIG. 6.—Case 4.

FIG. 8.—CASE 6.

CASE 4. A widow, aged sixty-six, complained of pain in the right flank of one year's duration. Plain x-ray plate showed an elongated shadow lying low in the pelvis and very suggestive of calculus in the ureter. On passage of a wax-tipped catheter, in order to confirm this finding, the shadow was found to be transposed upward as far as the kidney region, thus proving without doubt and without the necessity of scratches on the wax-bearing catheter that this shadow was in fact cast by a ureteral calculus.

B. X-RAY SHOWS NO SHADOWS.

CASE 5. A man of forty-five complained of attacks of pain in the left flank suggestive of renal calculus. The plain x-ray plate showed no shadow, but the ureteral catheter did not pass up the left side, and injection of bromide solution showed a definite defect in the outline of the ureter, which was also confirmed by scratches on the wax-tipped catheter.

CASE 6. A single woman forty years old complained of a dull ache in the left side of the abdomen of two weeks' duration. On examination by a physician a mass the size of an egg was found which was freely movable and without tenderness. There were no other symptoms,

and investigation of the intestinal tract by x-ray failed to show any abnormality. The urine was normal, as was also the renal function. Examination of the region of the mass by the plain x-ray plate showed nothing abnormal, but following the injection of bromide solution there was seen a definite defect in the outline of the ureter over a considerable extent. This was subsequently shown by operation to be due to a tumor primary in the ureter.

Kidney. A. X-RAY SHOWS SHADOWS.

CASE 7. A single girl of twenty-seven complained of attacks of pain in the left flank at varying intervals over a period of ten years. The urine was normal on examination, as was also the renal function. X-ray of the region of the kidneys showed multiple shadows extending vertically along each side of the vertebral column. These were very numerous and undoubtedly represented the calcification following the healing of a previous *tubercle mesenterica*. It was not possible, however, from this plate to explain the cause of the patient's pain, but on filling the urinary tract with bromide solution it became evident that the left kidney was hydronephrotic, due to pressure caused by a group of these calcareous glands.

CASE 8. In another case, that of a man thirty-five years old who complained of a symptomless mass the size of an egg which he had found in his left hypochondrium, the plain x-ray plate showed shadows of a like nature. Certain of these shadows had been misinterpreted by the roentgenologist, so that the first report was "Hydronephrosis due to renal calculus." On injection of the kidney, however, the outline was found to be entirely normal, and at operation the mass was found to be a broken-down tuberculous lymph node on the anterior wall of the abdomen.

CASE 9. A man twenty-six years of age complained of a dull ache in the right side of the abdomen during the previous month. Together with this there was marked increase in the frequency of urination during the day, but no change in the periods at night. The physical examination was negative except for a few white blood cells in the urine. The total renal function, as well as the divided function, was normal, and it was not possible to find the tubercle bacillus in the urine. The plain x-ray plates showed various shadows which were quite ambiguous in size and arrangement, and which on first inspection seemed most probably to be situated within the intestinal tract. Investigation of the kidney after it had been filled with a solution opaque to the x-rays, however, showed a deformity of the lower calix of the kidney, and subsequent operation demonstrated an occluded tuberculosis of the lower pole of the kidney with lime deposits to which the shadows in the x-ray plate had been due.

FIG. 11. Case 9.

FIG. 12. Case 8.

FIG. 16.—Case 10.

FIG. 15.—Case 9.

FIG. 17.—Case 11.

B. X-RAY SHOWS NO SHADOWS.

CASE 10. A girl of twenty-two complained of a dull ache in the right side lasting over a period of two or three years. She had been very carefully observed and never had any abnormality been found on physical examination except that at rare intervals the urine contained a very slight trace of albumen. Plain x-ray plate of the region in which the pain was experienced showed no abnormality. Injection of the kidney on this side, however, showed a large hydronephrosis, and subsequent operation demonstrated that this was caused by an abnormality of the blood supply to the kidney on this side, which caused obstruction to the outflow of urine by an artery which crossed the uretero-pelvic junction.

CASE 11. A married woman twenty-six years old complained of pain in the right side over a period of a year. At entrance to the hospital

she was having an attack of this pain with vomiting, but no chills or fever. The urine was normal except for a very rare white blood cell, and the total renal function was normal also. X-ray examination of the kidney and gall-bladder failed to show any abnormalities, but on injection of the kidney the pelvis was found occupied by a clear space around which the bromide solution cast a more dense shadow. This clear space was subsequently shown to be in fact a golf-sized stone lying in the renal pelvis and composed of pure cystin.

CASE 12. A woman twenty-six years old had had pain in the left lower quadrant of the abdomen and in the left leg, following a normal delivery eight months previous. These attacks of pain were severe and caused vomiting and confinement to bed. There was no fever or symptoms on the part of the bladder. Physical examination showed a small mass in the lower abdomen situated two or three fingers' breadth

FIG. 18.—Case 12.

below the umbilicus. On pelvic examination this mass could not be felt bi-manually. Renal function was normal and culture of the urine was sterile. Operation was undertaken with a diagnosis of ovarian tumor or cyst. Both ovaries, however, were found to be normal, but there was a small intramural fibroid in the fundus of the uterus about two or three cm. in diameter. This was removed and operation was followed by a normal convalescence. The patient, however, continued to have the same sort of attacks of pain, so that she entered the hospital again a year later. At this time investigation of the urinary tract showed a ptosis of the left kidney, and injection on this side showed hydronephrosis. This was confirmed by operation.

CASE 13. A man thirty-two years old complained of a dull ache low in the right back, which a few days before entrance became very acute and cramp-like. At this time the pain radiated across to the left side and caused nausea, but no vomiting. There was no difficulty on urination and no abnormality in the urine. He was supposed to be suffering from appendi-

cititis, and after the acute attack subsided his gastro-intestinal tract was examined by the x-ray. The report of this was that there was no abnormality except that there was some cecal stasis and a somewhat tender area in relation to the appendix, together with a little pylorospasm. The examination was otherwise negative. His pain continued, however, and on entrance to the hospital the urine contained a few blood cells, an occasional white cell and a slight trace of albumen. The renal function was normal. Although the plain x-ray plate showed nothing abnormal, injection of the kidneys showed a definite hydronephrosis. At operation the kidneys were found fixed at their lower poles (horseshoe kidney), the attacks of pain being due to an abnormal position of the ureter on the right side. This was altered, and the patient has since been entirely free from difficulty.

CASE 14. A single woman twenty-four years old complained of pain in the left side of the abdomen and back following a fall from a ladder six years previously. There had been repeated intermittent attacks of sharp left lumbar pain during the two years preceding her entrance to the hospital, and both she and her physician stated that she had repeatedly passed stones from the bladder and that the passage of these stones relieved the attacks of pain. Further, it was stated that on several occasions she had had hematuria and that she had been sometimes incontinent of urine while walking. She entered the hospital suffering from acute abdominal pain which ceased suddenly the following morning. Examination of her urine was entirely negative. Cultures were sterile and the patient had no fever. The total renal function was normal. X-ray plates failed to show any abnormality in the regions of the kidneys, ureters or bladder. She was discharged with a diagnosis of renal calculus, which had been passed previous to entry into the hospital.

Two months later she returned, complaining of the same type of pain. At this time x-ray plates, after injection of the kidneys, showed no evidence of remaining calculi on the left side, and, furthermore, the left pelvis was apparently absolutely normal. Specimens of urine from each kidney were also normal and cultures were sterile. The house officer's note at this time was as follows: "The patient's pain constitutes a perfectly definite indication for some radical procedure. She pleads for relief and therefore exploratory operation on the left kidney will be undertaken." This was accordingly done and the conditions found were, as may be surmised, entirely negative. The kidney was de-capsulated, however, and fixed in its position. Following a normal convalescence the patient returned again to the hospital four months later, saying that since her operation she had had four attacks of pain exactly the same as of old. This time she stated that during the pain she passes

FIG. 10.—Case 11.

FIG. 19.—Case 13.

no urine for a whole day. No stone appeared at any of these last attacks, but the patient was having acute pain on entrance and thought that she was again about to pass a stone. Cystoscopy was again undertaken, and as the instrument was about to be introduced a small round stone was found lying just within the vulval orifice. Ocular examination of this showed it to be without question a simple pebble, such as are used in large numbers in flower pots containing bulbs; and I at last saw the light. Subsequent chemical analysis of the stone thus naively submitted by the patient showed it to contain 96 per cent. silicon. The moral, of course, of this story is that in the presence of negative evidence nothing is ever gained by an exploratory operation. In fact today it may confidently be asserted to be practically true that so far as the urinary tract is concerned the operation which is frankly exploratory should hardly ever be undertaken.

DIAGNOSIS OF EARLY BREAST TUMORS, BASED ON THEIR CLINICAL PICTURE OR THEIR GROSS AND MICROSCOPIC PICTURE AT THE EXPLORATORY INCISION.*

Publicity. The writings of Samuel Hopkins Adams in 1913 in the *Ladies' Home Journal*, *Colliers'*, and *McClure's* magazines were the beginnings of a national campaign of education on cancer. This has been continued by the American Society for the Control of Cancer, culminating in Cancer Week last October.

This publicity has influenced many women to seek advice very shortly after their attention has been directed to the breast by pain, or feeling a lump, or noticing a discharge from the nipple. I called attention to this in 1916.³

More recently, in March, 1922,⁴ I recorded that among the last one hundred consecutive patients seeking my advice because of some trouble in one or both breasts, in about one-half, after examination, nothing was found which indicated operation. In the remainder there was at least one definite lump; at the operation in more than one-half the lump was not cancer, and among the cases of cancer in more than one-half the glands were not involved.

If we compare this experience of the first two years of this, the fourth decade, with the first decade up to 1900, one is astonished to find that in the group *benign conditions of the breast* for which no operation was done, the per cent. has increased from 2 to 50, while the per cent. of benign tumors operated on, as compared with the malignant, has increased from 10 to 50 per cent.

This change in the clinical picture and the pathology has increased the difficulties in diagnosis.

Benign Conditions of the Breast for which Operation is Not Indicated. I will briefly summarize what has been published in the *Journal of the American Medical Association*.⁵

These conditions are recognized from the clinical history, from inspection and by palpation.

Clinical History. If the patient is twenty-five years of age, or younger, the possibility of a malignant lesion can practically be excluded.

Pain. 64 cases. Pain in one or both breasts, of any character or duration, is not, of itself, an indication of a lesion for which operation is necessary; and if a lump is palpated, the presence or absence of pain is of no particular value in differential diagnosis.

A painful sear (22 cases), whether observed after the excision of a tumor of the breast, or of the breast itself, or whether it has occurred after the complete operation for cancer, is not, of itself, a sign of recurrence of the previous trouble.

*Read at the meeting of the Boston Medical Library in conjunction with the Suffolk District Medical Society, Feb. 23, 1922.

³Suggested by my colleague, Cullen of Baltimore.

Discharge from the Nipple. 36 cases. The history of a discharge from the nipple, no matter what its character, does not indicate cancer, nor necessarily a precancerous lesion, unless a definite lump is found at examination, or unless there is evidence of ulceration of the nipple, suggesting Paget's disease, and operation is not indicated.

Disappearing Tumor. 24 cases. If this history is obtained, and a definite tumor can be palpated, it suggests that the tumor is a cyst in chronic cystic mastitis.³

Inspection. Unilateral hypertrophy before, during, or shortly after puberty (12 cases) which, on palpation, reveals a normal breast, requires no surgical intervention. Symmetry is usually restored by the development of the other breast² (p. 559). The huge enlargement of both breasts (diffuse bilateral virginal hypertrophy, 5 cases) requires no treatment, except complete excision of both breasts when the size is a deformity and causes discomfort¹ (page 197, Fig. 442, and ² page 559).

If in the unilateral hypertrophy there is extreme pain and tenderness, there is apt to be a central adenoma which may not be recognized on palpation. The breast should be explored.

Unilateral hypertrophy of the breast in the adult is usually due to the presence of a benign adenoma, or sometimes of mastitis.

Retraction of the Nipple. Congenitally retracted nipples may be unilateral. This type of retraction can be differentiated from the retraction due to benign or malignant disease only by obtaining a definite history.

Recent unilateral retraction of the nipple, not associated with lactation, should be looked upon as a sign of cancer, and the complete operation performed. It is a rare finding without a palpable tumor, and now and then it may be associated with chronic cystic mastitis³ (Fig. 29).

Ulceration of the Nipple. 3 cases. Paget described a clinical entity. He observed women with definite malignant lumps in the breast, who gave a history of first a warty condition of the nipple, or an eczema which slowly developed into an ulceration and completely destroyed the nipple, and this change in the nipple had been observed one to three years before the lump in the breast was felt.

In the first twenty years of my experience, I observed Paget's disease only in this stage. I always subjected it to the complete operation; none were cured. In the past ten years, especially in the past five years, due to publicity, I have records of almost 15 cases of Paget's disease in its early stage when the lesion was confined to the nipple, and the breast contained no palpable mass. In all but one of these early cases the breast has been removed, or the complete operation performed. All of these patients are well. In the majority, the microscopic section shows a carcinoma of a definite type, be-

ginning in the epidermis of the nipple and growing down into the breast through the ducts. In a few cases the microscopic appearance was that of a benign inflammatory lesion, or a benign wart.¹⁰ In only one patient was the nipple excised. The sections showed early cancer infiltrating the ducts. There was local recurrence, followed by the complete operation and death from metastasis. In the past year I have seen one example of a benign warty condition and two of irritated nipples not associated with lactation in which there had been redness, desquamation, and some oozing of blood. In these three cases the lesions quickly healed after cleansing with soap and water and a protective dressing, and these patients have so far remained well.

From this thirty years' experience with over 20 cases, a definite rule can be deduced: Any irritated condition of the nipple which does not heal quickly after cleansing and protection should be looked upon as Paget's disease and treated by at least the complete excision of the breast.

Palpation. This part of the examination is essential and, more than ever before, is the trained sense of touch required to differentiate between a definite lump, for which immediate operation is indicated, and an indefinite one which is simply part of a lumpy breast. Then, when a definite lump is felt, the operator should be anxious to train his sense of touch to distinguish between the benign and the malignant tumor.

In some cases this has been impossible. But I have found in recent years that more and more am I able to recognize the malignant lump on palpation, and when I do explore a tumor, I find less frequently that I have made the mistake of considering it benign when it was really malignant. Every surgeon who keeps careful records can check the results of his diagnostic ability to distinguish the benign from the malignant tumors on palpation.

Findings on Palpation. I have classified definite tumors as follows:⁴

1. One definite tumor in one breast. *B.* One definite tumor in each breast. *C.* Multiple definite tumors in one breast. *D.* Multiple definite tumors in both breasts. The letter *e* after *A*, *B*, *C*, or *D*, indicates that the single or multiple tumors are indefinite.

Definite Tumors, Single or Multiple, in One or Both Breasts. If a single definite tumor can be palpated in one breast, operation is indicated immediately, if the patient is over twenty-five years of age, and, for additional safety, I have placed this age at twenty. If the patient is younger than twenty, the tumor small, not painful, not increasing in size, there is no danger in delay, and I have observed quite a few to disappear.

When there is a single definite tumor in one breast with no change in the nipple, no dimpling of the skin, no fixation of the skin, and no atrophy of the subcutaneous fat, the differential diagnosis rests upon palpation of the tumor only, and, as I have just indicated, it should be our ambition to improve this delicate sense of touch. Publicity will greatly increase the number of such cases.

Multiple Tumors. If there is a tumor in each breast, or multiple tumors in one or both breasts, this suggests benignancy, and if the patient is nursing her child, or there is a history of recent lactation, delay may be justifiable on the diagnosis of a galactoele. But, on the whole, it is safer to explore the most definite of the multiple tumors and be governed by the pathological findings. Personally, I have never observed carcinoma as a multiple tumor except when associated with definite clinical signs of malignancy such as changes in the skin or nipple. These multiple tumors are adenomas, lipomas or multiple blue-domed cysts³ (page 486, and Fig. 11).

When there is a history of a disappearing tumor or a history of an excision of a tumor proved to be benign, the subsequent development of multiple tumors in one or both breasts is an indication of benignancy, but unless one has had considerable experience, it is safer to explore.

Indefinite Tumors, Single or Multiple, in One or Both Breasts. I now have records of more than 50 patients whose breasts, on palpation, revealed no definite lump, and usually multiple indefinite lumps in both breasts. We may call the latter a "lumpy" breast.

These 50 patients have been followed, some for many years, and none have developed carcinoma. Undoubtedly some may, but the evidence seems to show that the women in this group run no more risk of cancer than any other woman of the same age.

In my study of chronic cystic mastitis³ (pages 489 and 497), I described 48 cases of non-encapsulated adenomatous areas (BB-13-4) in which, in the majority of cases, the tumors were indefinite and usually multiple in both breasts, and, in my opinion, operation was not indicated, and one or both breasts were unnecessarily removed. This pathological entity—an area of non-encapsulated adenoma—may produce a single definite tumor³ (Figs. 13 and 14).

When the tumor is indefinite, single or multiple, the gross appearance of these areas is beautifully pictured in Kelly-Noble,¹ Plate I, Fig. 1.

In the second group (BB-13-5³ (p. 497), there is, in addition to the adenomatous areas, one or more minute cysts, or one or more dilated ducts. Such an area may produce a single, definite tumor³ (Fig. 15), but in the majority of these 39 cases the tumors were indefinite and

usually multiple, and in these cases one or both breasts were unnecessarily removed.

I feel confident that the literature on the so-called chronic cystic mastitis has exaggerated its relation to cancer, and many surgeons have been influenced by fear rather than by fact; and even when only an indefinite area could be palpated, or multiple indefinite areas in one or both breasts, they have concluded that it would be safer to remove the breast and so protect the patient from cancer.

As I read my own evidence of thirty years, based upon more than 3000 cases, I am compelled to the conclusion that pain, discharge from the nipple and the palpation of one or more indefinite areas in one or both breasts, is not an indication for an operation, and that such patients run no more risk of cancer than any other woman of the same age.

But to distinguish between an indefinite and a definite lump in the breast requires experience and a trained sense of touch.

Unfortunately, surgeons with experience and this trained sense of touch have been misled, because when they have explored such an indefinite tumor, or removed the breast, their pathologists have reported to them that the lesion was adenocarcinoma, or "suspicious of malignancy," and this has been an obstacle to the proper development of differential diagnosis by palpation. I have discussed this in detail (3).

Worm-like Tumors Beneath the Nipple. This easily to be distinguished tumor is a definite clinical entity and has its positive pathology. It is due to the dilatation of the ducts beneath the nipple, and may be associated with a slight discharge from the nipple of brownish, or milk-like material, never of blood. I have described this clinical picture and pathology³ (page 500) from a study of 22 cases, with gross and microscopic illustrations. At the present time I have four cases recognized on palpation for which operation was postponed, and the palpable tumors disappeared. As far as I can make out, there is no relation between this type of dilatation of the ducts beneath the nipple and cancer, and when the worm-like mass beneath the nipple is recognized with certainty, exploration is not indicated. Cancer, however, very frequently begins in the nipple zone. But the tumor, on palpation, is an area of induration which should be easily differentiated from the soft, compressible, worm-like tumor, and as a rule the cancer is quickly associated with retraction or fixation of the nipple.

Diffuse Mastitis. I have discussed the definite tumor which may be felt in any part of the breast and which varies in size, shape and consistency. There is not space here to describe the different types. If this tumor cannot be distinguished on palpation, it must be explored. Then I have just pictured the special worm-like

tumor beneath the nipple, and now I would like to describe a third definite clinical entity, which should be recognized on palpation. I have called it *diffuse mastitis*.

This diffuse mastitis may be due to a diffuse non-encapsulated cystic adenoma, a definite type of chronic cystic mastitis. For its clinical and pathological picture I refer to the *Archives of Surgery* (page 528) (BB-13-8). This form of chronic cystic mastitis is known in the literature as Schimmellbusch's or Reclus' disease, and in 1916 I called it *scirrhous parenchymatous hypertrophy*.²

Briefly, there is nothing on inspection. On palpation, a quadrant, hemisphere, the entire breast, or both breasts, shows a definite thickening of the breast tissue; the involved breast has a palpable edge, like the liver or spleen; you can pick it up like a thick saucer, and in it you can palpate minute shot-like areas. If one breast is involved, it has been our rule to remove the breast, or to do the complete operation for cancer. In a few cases both breasts were involved and the bilateral operation was performed. In my communication in the *Archives of Surgery* I reported 13 cases. In one there was an area of cancer³ (Fig. 28), the glands showed metastasis, and the patient died of cancer. In the remaining 12 cases, of which two were bilateral, there was no positive evidence of cancer, and all of these patients have remained well.

In the past year I have repeatedly examined the breasts of three patients in which both breasts were apparently the seat of this type of chronic cystic mastitis. As I had never observed cancer in the bilateral type, I deferred operation under careful observation. In two patients the palpable areas have practically disappeared; in one, a recent case, it is still present.

This diffuse mastitis may be due to dilatation of the ducts in a quadrant or hemisphere of the breast. I have described my one observation in the *Archives of Surgery* (Fig. 19, page 511) (Pathol. No. 21192, BB-13-6). In this instance it could not be recognized from the diffuse type of chronic cystic mastitis until the breast had been removed.

Lactation Mastitis. During lactation there may be a diffuse mastitis of a quadrant, hemisphere, or of the entire breast, which never develops the clinical picture of an abscess, nor any changes in the nipple or skin. There is simply an area of induration, which, on palpation, is not unlike the diffuse chronic cystic mastitis except there are no palpable shot-like nodules. Although cancer of the lactating breast is infrequent, it does occur, and often it cannot be distinguished from this form of diffuse mastitis in lactation. When such breasts are explored, the gross and frozen sections give pictures difficult to differentiate the mastitis from the carcinoma. In all of these cases on my records the complete

operation for cancer has been performed, and I am inclined to think this is the safer procedure.

In lactation, an area of indurated breast due to so-called "caking" or pyogenic mastitis should do one of two things quickly: disappear or assume the clinical picture of an abscess and be incised. In a few rare instances this does not take place, and we are confronted with a diffuse area of induration. Of course, the probabilities are that this is mastitis, but the possibility of malignancy must be considered. I am inclined to think that in the future we shall be able to train ourselves to recognize the lesion by exploratory incision and the careful study of the gross appearance and the frozen section.

Fig. 1.—Pathol. No. 19740, Tubercular Mastitis of left breast. Female, aged twenty-eight; pregnant five months; diffuse infiltration of inner hemisphere; no change in skin or nipple. Exploratory incision—diagnosis cancer. Complete operation. The photograph shows the bulging of the inner hemisphere. See Fig. 2.

Fig. 2.—Pathol. No. 19740, Tubercular Mastitis of left breast. Cross section through involved hemisphere shows pregnancy lactation hypertrophy, diffuse infiltration, dilated ducts filled with milk like material. Microscopic sections—tuberculosis, no cancer. This patient is well six years after operation. Identical mastitis in right breast recovered without operation.

I had the opportunity to do this in three instances recently—all fortunately proved to be benign and the breasts were saved.

Tubercular Mastitis. In the early years of our experience, tubercular mastitis came under observation, due to delay on the part of the patient, with one or more sinuses. Then they came earlier, with the picture of a definite abscess. In my experience, sinus and abscess exclude carcinoma. When I wrote my contribution to *Bonnie's Surgery* in 1917, I had only observed tuberculosis of the breast (Fig. 565) in the stage of sinus or abscess. But when I corrected the galley-proof I had just observed a case of tubercular mastitis without abscess, without sinus, which, on exploration, resembled carcinoma, and was treated for carcinoma (Figs. 1 and 2). Since then I have seen two additional cases. We, therefore, must be prepared to meet tubercular mastitis before the stage of sinus or abscess which on palpation will give an induration of the breast difficult to distinguish from carcinoma and which will require more than the usual experience to differentiate it from cancer even at the exploratory incision and from the frozen section.

Non-lactation Mastitis. Trauma, injection of salt solution, pyogenic infection of the breast secondary to a focus elsewhere, such as the skin, osteomyelitis, may appear with the clinical picture of diffuse mastitis, presenting the same difficulties as lactation mastitis and tubercular mastitis. I have just observed such a case. But the x-ray showed a definite focus in the rib beneath the mastitis, which indicated that, if it was carcinoma it was hopeless, and for this reason I explored, and found a post-typhoid osteomyelitis of the rib infiltrating the breast.

Comedo-Adenoma.¹ (Fig. 479, p. 225) and ² (Fig. 345, page 612). This type of adenoma, as previously described, may occur as a non-encapsulated small tumor, or as a diffuse infiltration

of the breast, palpating like mastitis. It can always be recognized at the exploratory incision by the worm-like masses (Fig. 3) which express on pressure, but as it is frequently associated with cancer, it should receive the operation for cancer. I have records of 49 cases; 21 are of the pure, benign type, and all of them remained well; 28 were associated with definite cancer, and show the usual operative results of cancer.

Carcinoma Mastitis. Carcinoma may infiltrate the breast so rapidly that it gives the picture of a diffuse mastitis (Fig. 4) and in the

Fig. 4.—Pathol. No. 29602. Diffuse carcinoma of the entire breast. Upper view of fresh cut; lower view of older cut, showing a few comedones. Highest axillary glands involved. The patient died of metastasis.

early stage there may be no change in the skin or nipple. The late stage has been pictured in Fig. 515, page 245, Kelly-Noble.¹

Therefore, when we have the clinical picture of diffuse mastitis in one breast, we must always bear in mind that it may be diffuse carcinoma or comedo-adenoma and cancer, and for this reason, unless the surgeon is well able to recognize the benign form, it will be safer to perform the complete operation for cancer.

Single Definite Tumor Without Change in Skin or Nipple. Before proceeding with the description of the clinical picture and the pathology at the exploratory incision, I wish to call attention to the routine examination which should be made in every case of breast lesion on more than one occasion, and, if operation is to be performed, again on the operating table.

Routine Examination. The examiner should not know the history, or which breast is involved. The patient should recline on a couch, stripped of clothing to the waist, with the arms elevated above the head (Fig. 5).

One should inspect first the nipple, looking for warts, eczema, signs of discharge, retraction; the areola, the breast and the axilla. A visible

Fig. 3.—Pathol. No. 21085. Diffuse Comedo-adenoma and Cancer, involving entire breast. Cross section of breast shows the typical comedones. Microscopic sections show comedo-adenoma and cancer. See Fig. 15a.

fullness in the axilla extending beyond the outer and upper quadrant is due to breast tissue that not infrequently is present there. A visible small tumor is very suggestive of malignancy, except in the atrophic breast in patients with very little subcutaneous fat (Fig. 5).

FIG. 5.—The proper position for inspection and palpation of the breast. Inspection here shows benign warts of both nipples and a visible small tumor in the mid-zone of the right breast beneath the nipple.

Palpation. One should first palpate both breasts with both hands, feeling corresponding areas at the same time; then one breast with both hands, then with one hand. Every method of palpation should be employed. I find that palpating the breast with the fingers of one hand flat and moving the fingers up and down as when playing the piano is the best way to find the tumor.

When a definite tumor is found it should be studied as to its mobility, consistency and outline, its relation to skin, fat and nipple.

The breast occupied by the tumor should be pushed forward with the tumor to bring out dimpling. Fig. 6 (Path. No. 7973) [Previously reproduced in Fig. 597] shows early dimpling, while Fig. 7 (Path. No. 8579)² (Fig. 309) shows bulging without dimpling; here the tumor proved to be a blue-domed cyst.

In spite of a very large experience, and especially recently, with tumors in which there was no clinical evidence of malignancy, that is, no changes in the skin, subcutaneous fat or nipple, I do not feel prepared to write as yet this very important chapter on the diagnosis of breast tumors from inspection and palpation. The facts are that one cannot be certain; and unless there are definite signs of cancer, one should explore.

Clinical History. The reason for making the examination first and getting the history later is that publicity is bringing women for such an examination with conditions of the breast with which the majority of surgeons have had little

FIG. 6.—Pathol. No. 7973.—Palpation of the lump bringing out dimpling of the skin over the lump—an almost certain sign of cancer when the lump is outside the nipple zone.

or no previous experience, especially single and multiple indefinite lumps. The examiner, therefore, should not be influenced by any suggestion as to whether or where the patient or a previous examiner felt a lump. I have considered this part of the problem in detail in a recent paper in the *Journal of the American Medical Association*.⁴

I have also given there the facts in the clinical history which are helpful. They may be briefly summarized in the beginning of this paper.

Diagnosis at the Exploratory Incision. The patient should be prepared for general anesthesia and shaved and cleaned as for the complete operation for cancer. The breast and tumor should be again carefully palpated with the gloved hand.

There is considerable difference of opinion as to whether the tumor should be cut down upon or excised with a zone of breast tissue. I prefer and practice the former, reserving the latter for small tumors in very fatty breasts.

The former allows the immediate exposure of the tumor through the smallest wound and, theoretically, gives less opportunity for dissemination of malignant cells, if the tumor should prove to be cancer, and allows a more immediate and thorough chemical and thermal cauterization the moment malignancy is demonstrated.

The vast majority of benign tumors are either distinctly ENCAPSULATED ADENOMA OR THE BLUE-DOMED CYST. If all other types of non-encapsulated tumors, or cysts not of the blue-dome type, were treated as malignant tumors, the per cent. of women mutilated would be relatively small.

FIG. 7.—Pathol. No. 5279. Palpation of the lump showing bulging instead of dimpling of the skin. This is suggestive, but not positive of benignancy. In this case the tumor proved to be a blue-domed cyst.

The operator should then first learn to recognize the blue-domed cyst. This is not difficult, and I have discussed it in detail in the *Archives of Surgery*.³ The distinctly encapsulated adenoma should not be difficult to recognize. I have described it in *Binnie's Surgery*.²

Figure 8 (Path. No. 21193) illustrates a distinctly encapsulated adenoma bulging like a dome from the surrounding normal breast. All adenomas have this distinct appearance, no matter what their size. Demonstrating this, the encapsulated tumor should be excised with a

FIG. 8.—Pathol. No. 21193. A distinctly encapsulated adenoma surrounded by a zone of normal breast tissue.

zone of breast, as shown in Fig. 8, and then the operator should bisect the tumor, as shown in Figs. 9 and 9a (21193 and 20269).

Frozen Section. The objection to the frozen section has been fully discussed in my recent

FIG. 9.—Pathol. No. 21193. Bisecting of a distinctly encapsulated adenoma surrounded by a zone of normal breast tissue.

article in the *Archives of Surgery*.³ When pieces of the breast surrounding a blue-domed cyst and pieces of distinctly encapsulated adenoma are submitted to the pathologist responsible for the diagnostic work in the surgical clinics in this country, we find a marked difference of opinion, and when the diagnosis is "suspicious of malignancy," or "malignant," numerous breasts are unnecessarily sacrificed. Up to the present time I have numerous cases of both the blue-domed cyst and the encapsulated adenoma which have been diagnosed by a number of pathologists as malignant, but in which the operator has removed the cyst or the adenoma only, and there are no recurrences.

With these facts, which have been restudied again and again for a period of more than ten years, it is difficult to come to any other con-

FIG. 9a.—Pathol. No. 22269. Section of a distinctly encapsulated adenoma, surrounded by a zone of breast, the seat of early lactation hypertrophy.

clusion but that the exposure of a blue-domed cyst or of a definitely encapsulated tumor must be looked upon as a sign that the tumor is benign.

Non-Encapsulated Solid Tumors. The moment that the surgeon in exploring a palpable lump in the breast fails to recognize a blue dome

FIG. 10.—Pathol. No. 28540. Cross section through a non-encapsulated benign comedo adenoma. The markings are characteristic. If compressed comedones are exposed, as shown in Fig. 9c.

or a definite capsule, he has evidence that should make him suspicious that he is dealing with a malignant tumor; and unless he has been trained thoroughly to recognize the small group of non-encapsulated benign tumors of the breast, he should chemically or thermally cauterize the wound and proceed with the complete operation for cancer.

In the *Archives of Surgery*, I have illustrated and discussed the non-encapsulated adenoma (BB-13-4, 5 and 7), and since the publication of this article in November, a number of other cases have come under observation, but I will not discuss them here, but picture the larger and more important group of non-encapsulated malignant tumors.

FIG. 11.—Pathol. No. 28540. Microscopic section every 10 microns of pure benign comedo adenoma. For comedo and cancer, see Fig. 18a.

FIG. 12.—Pathol. No. 24144. Section through breast showing, to the right, circumscribed but non-encapsulated colloid cancer; to the left, breast tissue beneath the nipple. No evidence of chronic cystic mastitis.

Comedo-Adenoma and Cancer. I have records of 49 cases. The majority are small tumors, usually circumscribed. A few diffusely in-

volve the breast and appear clinically as mastitis (Fig. 3). This tumor should always be treated as cancer, because in 28 out of the 49 cases definite cancer was found microscopically. When the tumor is cut into (Fig. 10) (Path. No. 28540) it has a characteristic gross appearance—it is studded with granular areas from which worm-like masses can be expressed; it also has a typical appearance in the frozen section (Fig. 11) (Path. No. 28540).

This tumor should be as easy to recognize as the blue-domed cyst or the encapsulated adenoma.

Colloid Cancer. I have never seen this tumor encapsulated, but it is usually circumscribed. The moment one nicks it, its mucoid consistency is at once recognized. On its cut surface one sees gelatinous vesicles; it may be colored by hemorrhage (Fig. 12) (Path. No. 24144).

FIG. 13. Pathol. No. 7191. Microscopic picture of colloid cancer, showing the characteristic mucoid consistency of the tumor, with chronic inflammatory reaction in the stroma.

The microscopic picture, to one familiar with the tumor, should differentiate it from all other breast lesions (Fig. 13) (Path. No. 7101).

The only tumor which might be confused with the colloid cancer is the pure myxoma. I have observed but two cases—both were distinctly encapsulated, and the operators removed the tumors only. In my opinion it would be wiser to treat the pure myxoma as a colloid cancer.

I have just restudied the intracanalicular myxoadenoma. With rare exceptions it is always an encapsulated tumor. At first sight in the very myxomatous type it might be confused with the myxoma or colloid cancer, but its consistency is always firmer; gelatinous vesicles never form on its surface; it is not friable and never exudes mucoid material. As a matter of fact, rarely do operators fail to recognize the benignancy of the encapsulated intracanalicular myxoadenoma. Its microscopic appear-

FIG. 16.—Pathol. No. 29246. Small scirrhous cancer with typical radiating lines into surrounding breast fat. Tumor is more cellular than those shown in Figs. 14 and 15.

FIG. 14.—Pathol. No. 29309. Small scirrhous cancer in a fatty, cupping breast. No. 2, the cupping, and the pulling of the fat towards the small cancer. This tumor was some distance from the nipple.

FIG. 15.—Pathol. No. 27858. Small scirrhous cancer surrounded on three sides by fat. To the left, remains of breast tissue beneath a nipple. Note the branching lines from the cancer. One of the lines retracted the nipple, another draped the skin.

FIG. 17.—Pathol. No. 29360. Small circumscribed scirrhous to the left, without the radiating lines shown in previous illustrations; breast with a few dilated ducts to the right.

ance is also characteristic³ (Fig. 36).

Cancer. The small infiltrating scirrhous should never be mistaken. The surrounding breast tissue or fat is retracted towards it, giving it a star-like appearance (Figs. 14 and 15) (Path. Nos. 29309 and 27858).

Scirrhous cancer may be somewhat circumscribed, but even then we may see the fine lines of stroma extending from the tumor into the surrounding breast or fat (Fig. 16) (Path. No. 29246). Now and then the scirrhous is distinctly circumscribed and has not the star-like appearance as shown in Fig. 17 (Path. No. 29360). Scirrhous cancer usually cups on section; non-encapsulated benign tumors never do. It has a characteristic hardness; it gives a gritty sensation to the knife; granular material may be scraped from the surface. But in a few instances the hardness and the gross markings of a non-encapsulated tumor may closely resemble scirrhous cancer. [See illustrations in the *Archives of Surgery*² (Fig. 21) (Path. No. 17012).]

FIG. 18.—Pathol. No. 28940. Upper photograph shows section through nipple and breast; fibrous breast tissue surrounded by fat. Below, section of slightly infiltrating medullary carcinoma with a few comedones, surrounded by fat. For microscopic section, see Fig. 15a.

Medullary Carcinoma. This form usually occurs as a circumscribed tumor. The retraction and star-like appearance of the scirrhus are absent. It can always be distinguished from benign tumors by picking it with the knife, as it is always friable and granular (Fig. 18) (Path. No. 28940).

Cylindroma. This is a rare form of cancer, and is usually well circumscribed (Fig. 19) (Path. No. 21010). The frozen section, however, is quite different from the encapsulated adenoma (Fig. 20) (Path. No. 21010).^{5,6,7}

Cancer Cyst.^{2,5,6,7} A detailed discussion of this malignant lesion will have to be postponed. I have described it briefly in *Binnie's Surgery*.² The cancer cyst never has a blue dome. When it is nicked one can recognize malignancy by the thick wall or by the contents of the cyst, which is either blood or a thick grumous material.

The Benign Papillomatous Cyst.^{2,5,6,7} I find that this tumor has given operators more difficulty than any other benign lesion of the breast, because in the majority of cases they have either removed the breast or performed the complete operation for cancer. In my cases which I have explored I have never found a blue dome. The dome is gray. When opened, the cyst may contain blood, but one always finds within the cyst

a distinct papilloma. In cancer there is never a distinct benign papilloma. When the benign papillomatous cyst is excised with a zone of breast the wall of the cyst forms the base of the papilloma, and there has been no infiltration of the breast beyond. Now and then the entire cyst is filled with the compressed papilloma, and this tumor resembles closely the medullary carcinoma. It is only the distinct cyst wall which surrounds it that allows differentiation. Frozen sections of the papilloma within the cyst are very confusing.

The benign papillomatous cyst is not an infrequent tumor. I have records of some 45 cases, while during the same period we have about 34 cases looked upon as cancer arising in a papillomatous cyst. I believe, however, that a careful study of the cases, palpation before operation, and inspection at the exploratory incision should allow one to recognize the majority of the benign papillomatous cysts.

The important thing to remember is that when one is in doubt, the complete operation for cancer should be performed.

I have worked out roughly that if surgeons can recognize the blue-domed cyst, the distinctly encapsulated adenoma as benign, and remove the tumor only, and then follow the rule of performing the complete operation for cancer in all other cases, they will unnecessarily remove the breast for benign lesions in only about 15 per cent. of the cases. I am also inclined to the view that as they become more expert in palpation and pay more attention to the gross appearance they will gradually become able to recognize the distinctly benign non-encapsulated adenoma and areas of chronic mastitis and small areas of tubercular mastitis, and the distinctly benign papillomatous cysts. I am also inclined to the opinion that publicity will increase the relative proportion of these more difficult to recognize non-encapsulated tumors of the breast. My experience during the past two years confirms this belief. When I wrote my chapter in *Binnie's Surgery* in 1917 I had never seen tuberculous of the breast without sinus or abscess. Since then, with rare exceptions, tuberculous of the breast has presented itself clinically as mastitis or as an irregular palpable tumor, and when explored the usual gross appearance of tuberculous—abscess or caseation—was not seen. The non-encapsulated adenoma and areas of chronic cystic mastitis have increased rapidly in numbers since 1917. The most rapid increase has fortunately been in the blue-domed cyst.

Conclusions. Now that women are responding to the message of the profession in regard to lumps in the breast, and now that the general medical profession is no longer a party to delay, surgeons will see breast lesions in their earliest stages.

More attention must be paid to the clinical

FIG. 18a.—Pathol. No. 28940. Microscopic section showing carcinoma and comedo-adenoma.

history and to the examination by inspection and palpation, first, to exclude the group in which operation is not indicated; second, palpation of a definite lump must be developed to a method of greater precision; third, when tumors must be explored, surgeons must learn to recognize the benign type in which excision of the tumor with a zone of breast is sufficient for the protection of the patient.

For the present the mistake that should never be made is an incomplete operation for a malignant lesion. A mistake which is, and must be made, in a certain group of benign lesions difficult to recognize, is the complete operation.

I am inclined to the conclusion that the majority of trained surgeons can, and do, recognize cancer of the breast at exploration, and also the distinctly encapsulated adenoma and the blue-domed cyst.

We should encourage more detailed papers on the group of benign lesions difficult to recognize, because they are not encapsulated, or because they are not blue-domed cysts. For this reason communications, such as Dr. Lee's of New York, in a recent number of *Surgery, Gynecology and Obstetrics* on traumatic fat necrosis are of great value, and also the study of Kilgore¹⁰ on Paget's disease of the nipple, and a recent paper by Trout of Roanoke, read before the Southern Surgical Association, on the relation of malignant disease of the breast to pregnancy, and the excellent articles of Bartlett¹¹ from Terry's clinic in San Francisco.

There is ample material in the large clinics of this country to form the basis of such papers. Operators throughout the country need, and will welcome, helpful contributions of this character.

FIG. 19.—Pathol. No. 2010. Section of a circumscribed, but not encapsulated carcinoma of the cylindroma type, surrounded by normal breast. For microscopic section, see Fig. 20.

ADDENDUM.

Note: July 29, 1922.—Since this paper was read in February, five months ago, I have presented it to at least a dozen audiences, and the discussions lead me to emphasize the following points:

1. The examination should be made without any knowledge of the history or of the breast involved.

2. At the examination palpation is the essential feature. First, to differentiate the indefinite from the definite single lump and, second, having found a definite lump to try in every way to recognize any palpable sign of malignancy.

3. At the exploratory incision the blue-domed cyst and the encapsulated adenoma should be recognized by their gross appearance.

I have recently explored a cancer cyst which had somewhat the coloring of a blue dome, opening the cyst, it contained thick grumous material: wiping this out, nodules of cancer could be seen and felt in the wall. In a second cancer cyst explored in the same week, the dome was gray, not blue, the contents bloody: wiping this out, one could feel and see cancer nodules in the wall. Cancer cysts, therefore, can be differentiated from the blue-domed cyst by their contents.

The galactoceles has an opaque, white dome; its contents are creamlike or like milk. Cancer never appears in this form.

4. Scirrhus and medullary carcinoma are never encapsulated and have their typical gross

appearance as described and pictured in this paper. This is also true of the comedoadenoma, with and without cancer, and the colloid cancer.

5. When the explored tumor is not a blue-domed cyst or an encapsulated adenoma and not a cancer cyst, or a non-encapsulated area of solid cancer, it will appear as a non-encapsulated area, with or without minute cysts or dilated ducts. I have described these tumors in detail, in the *Archives of Surgery*³. Unless the surgeon has sufficient experience to be certain of the benignancy from the gross appearance, and frozen section, the complete operation for cancer should be performed. I am inclined to the view that, as surgeons and pathologists learn to recognize the gross and microscopic appearance of the various stages of so-called chronic cystic mastitis as a benign lesion, they will be able to differentiate the nonencapsulated tumor of the benign adenoma type from the same lesion with areas of cancer.

To repeat, until they are able to do this, all these lesions should be treated as malignant.

6. The recognition of the benign from the malignant papillomatous cyst apparently offers such great difficulties to the majority of surgeons and pathologists, that I reserve this problem for another communication.

7. Recurrence in, or in the region of, the scar is due to late intervention or bad surgery. I have had a large opportunity to observe the operations for cancer of the breast as performed in this country. My observations lead me to conclude that the surgery is good, but the bad results are due to late intervention.

8. To improve the results after operations for cancer of the breast, there must be earlier intervention of good surgery. This can be accomplished by publicity only. Good surgery will be of little avail without publicity.

9. The mistake that should never be made is an incomplete operation for cancer. The operation must never be in two stages.

10. The mistake that cannot always be avoided is the complete operation for cancer in doubtful cases.

As the operating surgeon pays more attention to gross pathology and has his tumors of the breast submitted for diagnosis to more competent pathologists, these mistakes in his clinic will be reduced.

11. When the surgeons of this country become as good diagnosticians as they are operators, I am confident that the number of women who lose their breast unnecessarily, will be reduced, and the number who are subjected to complete operation for tumors that are not malignant, will also be greatly reduced.

FIG. 20.—Pathol. No. 21010. Microscopic section showing cylindroma (a rare form of cancer of the breast) infiltrating fat.

DISCUSSION.

DR. S. RICH WRIGHT: Dr. Bloodgood has illustrated the way in which advances must be made in clinical pathology. The surgeon must become his own pathologist, or at least he must follow his pathologist through. It is a fact that many pathologists become more skillful with their eyes and fingers than many surgeons, and the secret of some pathologists' ability to make diagnoses from frozen sections lies partly in their ability to make a diagnosis with their eyes and fingers. The ability to interpret gross appearances is a great asset and every surgeon should become enough of a pathologist to do so.

Some of the points that Dr. Bloodgood brought up are easily explained pathologically; for instance, his criteria for the gross appearances of malignant

tumors, the contraction and the dimpling of the skin. New epithelial growths cannot grow independently of connective tissue. Newly formed connective tissue (i.e., stroma) must contract, and it is this contraction that produces the drawing in of adjacent fat tissue and dimpling of the skin.

Some of the slides that Dr. Bloodgood showed as doubtful cases of malignancy revealed the diagnosis of benignancy on the same slides. One, in particular, showed very definitely the smooth muscle accompanying the glands in the carcinoma-like area. Gland-like structures in adenomas of the breast, in growing, carry with them a supporting tissue which is a characteristic of gland structures from epidermal appendages, that is, a layer of smooth muscle. This was pointed out to me years ago by Dr. Mallory. In Dr. Bloodgood's slides the supporting elongated cells with very prominent fibrils—the smooth muscle accompanying the growth showed clearly. This characteristic structure is a very important criterion in the distinction between benign and malignant growths of the breast.

I do not know if Dr. Bloodgood meant to infer that patients who were alive many years after operation did not have malignant tumors. I think that some of these cases showing great injection of breast ducts by epithelium without stroma formation are most difficult to diagnose. Probably every pathologist remembers cases of proved malignancy where there was no demonstrable invasion of the connective or fat tissue in the initial growth. We have a belief that some malignant tumors may for a time grow entirely within the ducts.

DR. ROBERT B. GREENOUGH: We recognize that what we have heard tonight is the fruit of thirty years of remarkable industry combined with what is undoubtedly the most abundant material and largest experience in the surgical pathology of these diseases of the breast that there is. Dr. Bloodgood divides various borderline cases into a large number of different groups. Most of us have to content ourselves with the general statement that the epithelium of the breast in a woman over thirty-five shows an instability of growth which is a characteristic feature of that tissue. The expression of that instability of growth takes place in the production of a group of lesions, shading one into another, but verging more and more toward what pathologists like Dr. Wolbach recognize without question as cancer. The early stages of unstable growth may be either in the form of encapsulated tumors, or there may be diffuse changes throughout the breast which we, for lack of better knowledge, call cystic disease or chronic cystic mastitis. As those changes go on they appear to approach more and more toward malignancy, and although the estimated occurrence of malignant disease in these earlier conditions varies in different clinics they do not vary very much, and it is quite generally conceded that cancer is likely to develop in those cases if let alone and watched for an indefinite period. The doctrine in surgery for a long time has been that a tumor in the breast of a woman of cancer age should be regarded as malignant until it is proved something else, and no matter how skillful we may think ourselves in diagnosis from external examination, we must learn two things: first, that we are human and fallible and we may be mistaken in our diagnosis, and second,—a point which I don't think we always appreciate,—that even if we are correct in our diagnosis of a benign lesion, the fact that it is benign may give the individual assurance against the occurrence of cancer, which is false because later there may develop cancer reaching proportions such that radical cure is not possible, while the patient stumbles under the assurance that her condition is probably not malignant. It seems that those two possibilities are sufficient to justify operative treatment and the removal of tumors of the breast in women over thirty-five. Regarding the question of an explora-

tory incision and its safety or danger to the individual, it is generally conceded that to cut into a breast tumor, remove a piece of it, close the wound and send the tissue to the pathologist is bad for the patient. There is experimental evidence that a clean incision into a tumor may not spread the disease more quickly than it was spreading itself. On the other hand, trauma of any sort, massage or rubbing, will spread the tumor to its metastatic areas more rapidly than if let alone, so I think it is fair to say that any interference with the tumor should be avoided, but more particularly interference which involves a delay period before radical measures are employed. On the other hand, direct incision into the tumor can be done with the minimum of danger to the patient if it is necessary. If there is a strong suspicion of cancer, or if the diagnosis of cancer is made in an older woman, there is ample justification for treating it as cancer, but in younger people an exploratory incision is a measure which can be done with safety. In our series from the Massachusetts General Hospital, cases from 1912 to 1914, there were four in whom that was done. They were favorable cases. They were all explored, at the operation the diagnosis was confirmed, and the operation completed, and all four cases were well six or more years after operation. Of the two cases in which operation was done in two stages, with a period of delay between, both were dead within a year.

DR. F. B. LUND: I must join the other speakers and thank Dr. Bloodgood for many years of most valuable instruction, not only in breast tumors, but also in the pathology of bone. These radiating lines of fibrous tissue Dr. Wolbach has spoken of, that draw in through the fat to the cancer, give the tumor itself a certain angular feeling, and I think that, as a general principle, cancerous tumors feel irregular and angular in shape while benign tumors do not. A man who has seen a good many of these cases and has followed the pathological diagnosis through and seen the sections, can make a better diagnosis on the gross section than the average man can on the frozen section. I do not mean the section sent to the pathologist carefully stained and examined, but the frozen section. The pathologist does not always succeed in making the section in the place where the cancer may be, and an experienced surgeon can, in 25 out of 100 cases, tell what the thing is. On the other hand, I do not believe in cutting into these tumors if you can possibly help it and there are only a few of them which you will have to cut into to decide whether it is cancer or not. If you have to do this, you should go over the surface with a cautery before you proceed with your radical operation. Never do a two-stage procedure of sending a specimen to the pathologist and having it come back. Of these little fat necroses which have been described by Dr. Lee of New York and which Dr. Bloodgood mentioned—I have had two cases; one was in a woman with a cancer on whom I did a radical operation, and I was very well satisfied with the prospect. Within six months she came back with three or four little lumps under the skin like lima beans. I could not think of anything but recurrence, but when they were taken out they proved to be necrotic fat. The other case of fat necrosis occurred in the breast of a woman who had had a uterine operation with hemorrhage and had a needle put into the breast for the injection of salt solution. I removed the breast tumor, which showed at operation what it was.

DR. BLOODGOOD (in closing): I would like to express my appreciation of Dr. Wolbach's remarks. He belongs to the younger generation of pathologists and I don't know that I have ever heard anything from the clinics in general pathology which pleases me more than what he has said. I believe it is the beginning of team work between surgeons interested in pathology and general pathologists. We all agree that the Medical School must have the university

atmosphere and I think that those who do the work chiefly in pathology and physiology need contact with the practical side of things, and those who work on the more practical side need the help of the scientific side of medicine. In the past the team work of the practical man and the scientific man has not been as good as it should be. He is the first general pathologist, as far as I know, who has said the surgeon ought to be his own pathologist. I am particularly interested in what he says of the presence of smooth muscle. It is just those little things we need to know in our diagnosis.

I want to call attention again to what Dr. Greenough said about the nature of certain changes we find in the breast. We do not know whether they are cancer or precede cancer. If publicity brings every woman to us the moment she feels a tumor and we do a complete operation for cancer and that tumor is cancer and the glands are not involved, the best we can offer is 70 per cent. A comparison with our figures (and we have a very large group) with Dr. Greenough's figures shows that they are practically identical.

VARICOSE VEINS AND ULCER: METHODS OF DIAGNOSIS AND TREATMENT.*

By JOHN HOMANS, M.D., F.A.C.S., BOSTON.

[From the Surgical Clinic of the Peter Bent Brigham Hospital.]

THE operative treatment of varicose veins of the legs has never had a very good name. The palliative treatment requires a good deal of effort to accomplish very little. Many patients are able to enjoy life with no treatment at all. It may be that the time, thought and skill, which successful surgery requires for the relief of a common condition annoying as a rule rather than incapacitating or dangerous, is not fully realized either by the laity or the profession. In this instance even more than in most surgical diseases it is true that routine operations will cure the average patient but that unusually careful treatment alone will secure the high proportion of good results which represents successful surgery. The reasons for this statement will be made clearer when the nature of the condition and the principles upon which its treatment is based are considered.

ANATOMY.

Anatomically, the veins in which we are interested are the great and lesser saphenous systems, which carry the returning venous blood from the superficial tissues of the lower leg (Fig. 1). The great or internal saphenous vein collects tributaries from the front and inner side of the calf, and passing up the thigh as a large single trunk, empties into the femoral vein at the saphenous opening. The lesser or external saphenous drains the back and outer side of the calf and joins the popliteal vein in the upper part of the popliteal space. All the veins of the legs, like

FIG. 1.—The superficial veins. The great or internal saphenous vein and its branches. Note the position and relations of the perforating veins. The lesser saphenous which drains the back of the calf, emptying into the popliteal vein, is not shown. (Published by courtesy of *Surg., Gynec., and Obstet.*, 1916, xxii, 143-155.)

those of the arms, are furnished with bicuspid valves so set as to allow the blood to flow only toward the heart.

As a sort of safety vent for the surface veins a number of short vessels pass from the larger trunks in the calf to the deep veins which accompany the great arteries. To reach the deep veins these vessels necessarily perforate the fascia covering the muscles, and their valves are so set as to allow blood to flow only from without inward, that is, from the surface to the depth.

As to the deep veins, it is only necessary to realize that since they care for the very active muscles of the calf and thigh they must carry a considerably larger volume of blood than those of the subcutaneous tissues. They are quite capable of disposing of the surface blood when the superficial veins are disabled.

PHYSIOLOGY.

Physiologically, the means by which the blood is carried up from the legs to the heart is particularly interesting (Fig. 2). There is, of course, a slow push from the capillary circulation. There is also suction from above, trans-

*Read before the New Hampshire Surgical Club, West Manchester, April 17, 1922.

FIG. 2.—Diagram showing the normal direction of blood current in the superficial and deep systems. Perforating veins connect the two and carry blood toward the deep vessels only. The diagram suggests roughly the relative capacity of the two systems. The free anastomosis between them in the foot is indicated.

mitted through the great abdominal vessels by the rhythmic pumping of the breathing and the action of the heart itself. But the force mainly responsible for sending the venous blood along lies in the action upon the vein walls of the muscles of the legs. The valves of the veins divide them into a series of chambers. Blood can pass up from one chamber to another but never back. Therefore any muscular motion which compresses any segment of a vein will force blood into the segment next higher. With this mechanism the main channels are most concerned and for it they are particularly adapted, since every entering branch has a valve at its root, and thus none of the muscular energy is wasted in driving blood from the large veins back into their tributaries. It is easy to see that in comparison with the deep veins, the surface vessels are at a real disadvantage. The deep veins are surrounded by muscle or lie between muscle and bone. This muscular pressure is applied to them directly. The surface veins lie in the superficial fat outside the deep fascia and are covered only by the skin. Therefore their walls are less actively supported and the pressure by muscle contraction acts on them

only because they are enclosed within the comparatively inelastic skin. It is doubtless to make up for this inferiority that the perforating veins of the lower leg are supplied. No one need doubt the importance of muscular movement in the venous circulation of the leg who stands perfectly still long enough to feel the tingling discomfort of the ensuing engorgement.

ETIOLOGY.

If we consider, as we certainly should, that a varicose vein is simply one whose valves are broken, it is easy to understand how the wear and tear of life brings about the disease. The weight of the column of blood resting upon any one valve is something which it can bear very comfortably, but let this strain be unduly prolonged as in occupations which require long standing, or let it be magnified by anything which forces back the blood column, as in conditions of increased abdominal pressure, and valves are apt to give way. When the abdominal muscles are set, as in heavy lifting, there is added to the weight of the blood column above the topmost valve, in the case of the femoral or the great saphenous vein, this increased intra-abdominal pressure. You may sometimes notice even on coughing a slight enlargement and a definite palpable thrill in the great saphenous vein just below Poupart's ligament. When there is no evidence of varicosity at a lower level this phenomenon may lead you to a diagnosis of femoral hernia.

We start life with fifteen to twenty valves in the main saphenous trunk from ankle to groin. There is usually additional protection in the presence of a valve in the femoral vein above the entrance of the saphenous. Since the great abdominal veins have none, increased abdominal pressure acts first on the topmost valve and here the breaking down in all probability begins. Thus the occupations calling for heavy and sustained lifting are usually responsible for the varicose veins of men. In women the association of the varix with pregnancy is exceedingly common, though just how the engorgement of the surface veins is brought about, as it frequently is, in early pregnancy before abdominal tension is much increased, is not at all clear.

Varix may originate in two other ways. In some individuals of either sex it appears in youth or at the time of puberty, presumably on account of some malformation of the vein walls or of the valves themselves. But the most distressing form of varicose veins, the one most intractable to treatment and prone to ulcer, arises from phlebitis, such as the milk leg after childbirth, or the phlebitis of typhoid fever. The infection and clotting are followed by a restoration of the main channel, but the valves are usually crippled and the vein walls thickened. Such veins, though small, are just as

"varicose" as the large tortuous vessels which are so familiar.

PATHOLOGY.

Only a word about pathology. As the valves fail, the veins dilate, and the nutrition of their walls suffers. Scar tissue begins to replace their smooth muscle and elastic fibres. They become elongated and distorted. Thus tortuous and sacculated areas are formed. Even calcification may occur. In such veins the blood can pour down more easily than it can mount up, and until elevation of the legs enables it to pass along or until it is slowly pushed up by the capillary blood behind, it stagnates (Fig. 3).

FIG. 3.—Diagram showing the direction of the blood current in varicose veins. Blood flows down the surface veins. The perforating veins carry blood from the varicose surface vessels to the deep system. The deep veins do additional work.

The pressure within such vessels is increased according to the height of the column of blood above any given point, but on coughing or straining it is, of course, enormously magnified. Hence, the occasional rupture of a varicose vein. If the perforating veins are equally varicose, as may occasionally be the case, stagnation and back pressure are still farther intensified, since the deep veins, which, practically speaking, are never diseased, cannot then help, and may even contribute some of their load to

FIG. 4.—Diagram showing the direction of blood current in superficial varix with incompetent perforating vessels. The perforating veins add to the disability of the surface vessels.

surface vessels (Fig. 4). When, however, the perforating veins are competent, and particularly when varix develops slowly, there occurs what amounts to a collateral circulation (Fig. 5). This may be so efficient that the only sign of varix is a single great tortuous trunk passing down the thigh to the inner calf and ankle. The skin of the entire area may then be well nourished. But if the stasis is more widespread and considerable areas of skin are bathed in stagnant blood, other changes follow which lead to ulcer.

ULCER.

Ulcer is the most common complication of varicose veins. To establish it an injury plus infection is necessary, but the stage is always set. The first sign of impending ulceration is usually the pigmentation which appears in larger and smaller patches upon the front and inner sides of the lower leg (Fig. 6). This is the region of greatest stasis since the long column of blood reaching to the heart is above it and there is not the free anastomosis with the deep circulation which is present in the foot. The appearance of pigment, which is often ac-

evitably becomes infected. The extent of the ulcer then depends upon the degree of malnutrition and upon the character of the treatment which is used.

FIG. 7.—Varix complicated by ulcer. Note the relation of the ulcer on the right and the pigmented area on the left to the varicose veins. Compare with Figs. 8 and 9 for demonstration that the perforating veins of the left calf are competent.

DIAGNOSIS. (Fig. 7.)

The appearance of fully developed varix is so unmistakable that only the refinements of diagnosis are important in coming to a decision as to the treatment. Since the blood readily pours down a varicose vein, the simplest test of the loss of its valves is suddenly to lower the leg which has previously been emptied of blood by elevation. This is easily done by placing the patient in a rocking chair, raising the leg as the chair tips back, and asking the patient to stand up as the chair tips forward (Fig. 8). The test was devised by Trendelenburg, the author of the position used so generally in abdominal operations upon the pelvis. The veins, of course, stand out tensely as the patient stands. But there is a very obvious refinement of this test which gives even more information. Before the leg is lowered, pressure is made upon the great saphenous vein in the thigh sufficient to prevent the flow of blood down it. When the patient stands, the vessels remain collapsed below the point of pressure and fill with a shock when the pressure is removed. This test is most conveniently carried out by passing a short length of gauze bandage about the upper thigh. The ends of the bandage are held as reins are held in one hand in driving. A half twist of the hand gives sufficient constriction and release is easily made (Fig. 9).

Suppose now that as the patient stands, the constriction is not released but maintained. If then the veins are seen and felt to fill quite rap-

panied by a shiny atrophy, is evidence of the irritation due to poor nutrition. Only a scratch or a blow is necessary to establish an ulcer, for the badly nourished tissue almost in-

FIG. 8.—The same patient shown in Fig. 7. The varicose veins have been choked of blood.

FIG. 9.—Demonstration of the constriction test. The same patient shown in Figs. 7 and 8. Note the constricting bandage about the upper thigh and the method of tightening the bandage. The varicose veins remain empty below the constriction at the end of half a minute.

idly below the constriction, they obviously have not filled with fresh blood from the arterial circulation, since this is a slow process requiring perhaps three-quarters of a minute. Nor have they filled by downflow from above, since the bandage prevents it. Therefore they must have filled from the deep veins by leakage of the valves of the perforators which normally, as you will remember, conduct blood only from without inward. This incompetence of the per-

forating veins indicates a greater gravity of the condition and is particularly important in planning the treatment of ulcer. For, if, as sometimes happens, an ulcer lies directly over one of these vessels, and if at operation only the superficial veins higher than the ulcer are removed, the presence of the leaking perforator will continue to lead to stagnation of blood in the region of the ulcer and failure to cure. However, even in varix uncomplicated by ulcer, the test may be valuable. The lesser saphenous vein perforates the popliteal space. Its branches on the back of the calf may, without showing much enlargement, communicate with the great saphenous. If it is varicose, it may alone be responsible for the filling of the surface veins below the constriction in the thigh. If early filling below the constriction is evident and varicosity of the lesser saphenous is suspected, the same test can be applied at the level of the knee. If constriction here now checks the filling below, the lesser saphenous is the leaking perforator and must be removed. It is not rare to find recurrences after excision of the great saphenous vein from failure to deal with this vessel.

Now to go back a moment. We have just followed the course of events when the superficial veins fill below the constriction upon lowering the leg and we have seen that such filling indicates a leak into the surface vessels from the deep. If, on the other hand, the superficial veins remain empty for a half minute or more after the leg is lowered, there is no such leak. We are then dealing with a pure surface varix and the treatment even in the presence of ulcer is simplified.

TYPES OF VARICOSE VEINS.

The relation to treatment of the examinations I have just described may appear more obvious if there is kept in mind a picture of the various types of varix. The common type, of course, shows the large dilated tortuous veins with which we are all familiar (Fig. 5). The plexus of large veins is most evident on the inner side and front of the calf, but the tortuous channel of the main vessel is frequently noticeable in the thigh as well. In women, whose subcutaneous fat is more abundant than that of men, the varicose vessel in the thigh is frequently palpable rather than visible. In that case its position may be detected by locating the impulse set up by tapping the tense veins of the calf, a procedure known as the Schwarz test. In men, however, the great saphenous vein is usually visible up to the saphenous opening, where a large sacculation is often present. Of this familiar type it may be said that the worse it looks the easier it is to treat. For while the varicose condition of the principal superficial vessels is gradually becoming established, there is usually developed sufficient compensatory circulation outside the great saphenous system to keep the skin well nourished. The

perforating veins are usually competent. The most the patient suffers from is a feeling of fullness and discomfort on long standing. When ulcer does occur, it usually "rides" upon a large vessel, and, unless it has been long and badly infected, is easy to cure. The Trendelenburg test shows immediate filling of the veins on standing. The constriction test shows, in most instances, no filling of the vessels below the constriction when the leg is lowered, since the perforating veins are normally fulfilling their function. Indeed, you will occasionally see a patient in whom the perforating veins are so efficient in their rôle of safety valve that, even in the fully erect position, the surface vessels remain relaxed below the constriction in the thigh for long periods.

The contrast to the common type is seen when varix arises after a phlebitis or when phlebitis attacks veins already more or less varicose. In such conditions the surface veins are often so scarred and shrunken as to be invisible. They may usually be palpated, however, as hard cords. Such dilated surface veins as may be evident are not the principal channels but distended tributaries ordinarily insignificant. Often it is not the visible veins which call attention to the disease, but the ulcer or ulcers which almost in-

FIG. 12.—A "freak." A varicose vein tributary to the gluteal vessels. In the thigh it is associated with a nœvus which extends from the outer upper thigh to the front of the patella.

FIG. 13.—Post-phlebitic varix. Note the absence of visible veins and the extensive areas of pigmentation.

variably complicate it (Figs. 10 and 11). Indeed, I venture to say that a diagnosis *not* of varicose veins and varicose ulcer, but of syphilitic ulcer is commonly made in such cases. I happen to have seen a considerable number of them, have found the Wassermann reaction neg-

ative, and have usually been able to get the history of phlebitis which confirms the diagnosis. Apparently two factors contribute to the formation of ulcers in these unfortunate patients. One is the quite general infection of the calf which accompanies the phlebitis and leaves the tissues badly scarred and poorly nourished. The second is the very common involvement of the perforating veins in the phlebitic process. Stasis and malnutrition are therefore magnified. Ulcers are common, often diffuse, and occasionally multiple. It is in this type of varix that the constriction test most often discloses rapid filling below the constriction. The test must often be made more by the sense of touch than by the sense of sight, since the surface veins are so often sclerosed and inconspicuous. In some instances, the filling of the veins on standing is equally rapid, whether the main vessel in the thigh is free or compressed.

The third type takes in what may be called the freaks (Fig. 12). This includes the unusual dilatations of vessels of the outer leg and thigh independent of the great or lesser saphenous systems. It includes such general dilatation of all the surface veins of the lower extremity, and of the abdomen as well, as arise without obvious cause. And it includes varix of the lesser saphenous vein alone, a condition hard to explain on a basis of back pressure, since one would expect the great saphenous system to be involved in all instances before the lesser.

This sketch may perhaps make clearer the reasonableness of studying and analyzing the con-

ditions present in any given patient suffering from varicose veins or ulcer. The importance of an accurate diagnosis will appear even more obvious when the choice of treatment is considered.

AMBULATORY TREATMENT.

First, a word about palliative treatment. This consists in so compressing by bandages the dilated surface vessels that they are kept emptied of blood. In this way the patient's sense of fullness and tingling is relieved and the blood is actually forced into channels capable of carrying it toward the heart. Efficient bandaging, and by the word I mean to cover the use of elastic or canvas stockings as well as of gauze and flannel rollers, may prevent the development of ulcer and will usually cure it when present. Soap and water cleanliness of a varicose leg is an indispensable accompaniment. The particular ointment applied to the ulcer is far less important than the pressure of the bandage. And in any case, no bandage, however efficient, can approach the effect of rest in bed.

If a varicose ulcer must be treated in the ambulatory manner, a most satisfactory arrangement is the use of the so-called "jelly" bandage. This consists of several layers of ordinary gauze bandage permeated with Unna's paste. An excellent formula for this paste is:

Zinc oxide,	10 gm.
Gelatin,	40 gm.
Glycerin,	120 cc.
Water,	150 cc.

The gelatin is dissolved in hot water by heating. Mix the zinc oxide with the glycerin. Put all ingredients together and let stand until hard, occasionally stirring. In hot weather the gelatin may be increased at the expense of the glycerin.

To be used, the paste is heated in a water bath until it liquefies, and is then applied as follows: The leg, which has been elevated for some time, is painted from toes to knee with the liquid paste. To this surface a smooth layer of gauze bandage is applied. Upon this, a second painting of paste is laid on, and in this way, three or four layers of bandage impregnated with paste are smoothly fitted to the leg. The heel is not included. After a few hours of drying, the jelly bandage is comfortable, flexible and very durable. It may remain in place for several weeks. The ulcer, if small and little infected, may be directly and permanently covered, but it is usually wiser to cut a window over it for the purpose of making local applications. The jelly bandage can also be used with advantage in convalescence from operation, especially when the patient is first getting about. In general, it may be said that though this particular dressing requires some practice and skill in application, it is far superior in every way to ordinary bandaging. But however successful any form of palliative treatment may be, it

FIG. 11.—Post-phlebitic varix. Note the crease on the inner face of the calf as evidence of the adhesion of the skin to a small thick-walled vein beneath. No veins are visible. The ulcer is directly tributary to the vein indicated by the crease.

never alters the basic varicose condition, and only while it is maintained does it prevent the recurrence of ulcer.

OPERATIVE TREATMENT.

Operative treatment aims to do away altogether with varicose veins. To be successful it must permanently break the column of blood between the great abdominal veins and the superficial circulation below. It only removes what is worse than useless, the varicose channels down which blood has been pouring to increase the labor of the deep veins. The work of the latter, far from being increased by excision of the varicose surface veins, is thus actually lightened. In carrying out the operation one should bear in mind, first, that the great saphenous vein must be most thoroughly eradicated at its upper end; second, that all wounds must heal perfectly; and third, that ulcers must be so treated that they cannot recur. Let us take up separately these three requirements.

The Removal of the Great Saphenous Vein. Recurrence after operation comes most often from a reestablishment of connection between surface veins remaining in the leg and the stump of the great saphenous. Therefore the vein must be tied and divided close to the femoral, and the several small branches which enter it in this region, both from above and below, must be disposed of as well. This is most conveniently

done through an oblique incision several inches long just below and parallel to Poupart's ligament. From this point on, the main channel may be stripped or excised by open dissection to a point below the knee. To all intents and purposes this is the whole operation. The removal of the distended veins of the calf, once all danger of back pressure from above is at an end, is only essential when incompetent perforating veins have been shown to be present. Both operator and patient are usually better satisfied, however, if the lower leg as well is dissected.

The Prompt and Sound Healing of Wounds. Wounds of even normal legs heal perhaps a little less well than those of less dependent parts. Wounds of varicose legs are at a still greater disadvantage. Therefore if operations are to be uncomplicated by sloughing and infection and to lead to quick and complete healing, the tissues must be handled with the greatest gentleness and cleanliness. Incisions should always be carried down cleanly to the deep fascia. The skin edges should be held open with retractors and not continually seized with forceps. When a tortuous adherent vein is to be removed, it is better to turn up a thick flap and to remove the vein from underneath it than to follow the vein from the surface. This is particularly true and important for the calf, since the thigh vein is most easily eradicated with the Mayo stripper. In any case, it is most unwise to make an incision of any sort on the inner side of the knee, for a thick and unstable scar is apt to result. Use fresh sets of forceps and haemostats frequently. Seize the smallest possible bite of vessel in your haemostat. Use fine ligature material and leave wounds dry and without dead space. Then incisions will heal perfectly. There is almost no surgery in which poor technic is more heavily penalized. If you can perform a complete excision of the varicose great saphenous vein in an hour you will be operating quickly.

The Treatment of Ulcer. It is here, above all, that variations in treatment according to the tests already described may profoundly influence the result. Suppose that a small and not particularly indurated ulcer "rides" on a large vein in the calf. The tests show that on lowering the leg while constriction is applied to the surface vessels in the thigh, the veins of the calf remain empty for a half minute or more. There are then no incompetent perforating veins. The usual operation of excision down to the ulcer region is carried out. It is unnecessary and undesirable to follow the vein through the ulcer or to excise the ulcer, since removal of the engorged vessel down to a point immediately above will cause it to heal permanently. Under the same conditions, but with a large and very much indurated ulcer, the decision may be more difficult. Here the infection and scar may be so deep that even removal of the vein which, so to speak, feeds it will not alone insure healing. The

ulcer may then be excised, and if the wound edges cannot easily be approximated, the raw surface should be skin grafted.

But now suppose that the tests disclose the presence of leaking perforating veins. The ulcer area may be widely pigmented and scarred. There may be one large or several small ulcers. Such are the conditions which frequently arise after phlebitis. Whatever decision is then come to in respect to the treatment of the ulcers themselves, the veins of the lower leg must be fully dissected and, as far as possible, the perforating veins found and tied on the deep fascia. This may mean dissecting in densely scarred infected tissues. It will usually mean the excision of ulcers down to sound tissues even if the dissection exposes bone, muscle or tendon sheath. Such dissections require the greatest gentleness and patience. Wounds must be very loosely closed. Operations may have to be done in more than one stage. The time and trouble is well spent if a working man or woman is given a sound, useful leg.

PHLEBITIS.

There remains to be discussed the treatment of phlebitis. I have already described the conditions which may arise after an acute inflammation of previously normal veins. During the attack itself the inner side of the thigh and calf are often red, swollen and tender. The veins themselves are clotted. The lower leg is infiltrated and oedematous. Evidently the process is a pretty general one, and I do not believe that at this time anything in an operative way can do other than harm. Elevation and rest alone are indicated. Even as the process subsides the most which can be done is directed toward the palliation of future trouble. To this end the patient should not use the leg at all until all signs of inflammation are gone. From then on for several weeks exercise of the leg in bed may be permitted. While getting up, the leg should never be allowed to hang down. Walking is better than standing. If swelling occurs, the leg must be kept elevated in every idle moment. Bandaging may be of great assistance. Probably the venous surface circulation is never to be what it was, though the deep circulation is rarely disturbed. In milder cases no permanent bad effects beyond a little swelling on long standing may be left. But when the infection and clotting have been widespread, the ulcers of the type I have already described are prone to occur even within a few months. No time or trouble is badly spent which mitigates at all the complications of phlebitis.

The phlebitis of veins already varicose is a different matter. The dilated vessels are tightly filled with clot; the skin about them is often red and oedematous; but the process is comparatively local. The acute stage usually subsides rapidly upon rest in bed though suppuration in some one part occasionally occurs. On the whole,

as soon as the worst of the process is over the best treatment is probably excision of the thrombosed veins. The only danger is the possible presence of the clot in the region of the saphenous opening, for in dividing and tying off the stump of the saphenous vein, a portion of the clot may perhaps be forced into the femoral. In that case a fatal pulmonary embolism will result. It is a safe rule, therefore, to postpone excision if thrombosis is evident as high as this point. Excision of the varicose veins should not even then, however, be abandoned since phlebitis is very likely to recur; and moreover, though one might expect the organization of a clot to lead to obliteration and so to the cure of varix, it never does so. When operating upon the thrombosed vessels, the inflamed skin adherent to them must be removed at the same time. Thus, unusual care in making and closing wounds is essential. In spite of this difficulty, operations for the removal of clotted varicose veins are remarkably satisfactory. They will usually save the patient considerable time and suffering.

SUMMARY.

Varicose veins of the legs are valveless superficial veins no longer able, when the body is upright, to carry blood in the direction of the heart.

The cause of varix is usually hard physical labor or childbearing. The valves may be destroyed by phlebitis, in which case the soft tissues of the legs are left more or less inflamed and scarred. Rarely and without known cause, the veins become varicose in early life.

The great saphenous vein, draining the superficial tissues of the inner side and front of the thigh and calf, is the vessel almost invariably affected.

It is possible by appropriate tests to determine the completeness of surface varicosity and to decide whether the perforating veins are diseased.

The deep veins are almost never varicose and may be counted upon to carry the load of the surface circulation.

Varicose ulcers occur because (1) the skin associated with varicose veins is often badly nourished, and (2) because it is easily traumatized and infected.

The familiar large tortuous type of varicose vein is readily cured by appropriate operation.

Ulcers are to be treated more or less radically according as varicose perforating veins are present or absent, and according to the degree of infection and induration surrounding the ulcer.

Post-phlebitic varix is to be diagnosed by a history of phlebitis, the presence of small sclerosed veins, and, in advanced cases, by the large amount of diffuse induration and oedema of the calf. Ulcer usually is present in this disease. It is intractable to palliative treatment and al-

most invariably requires excision. Operations upon post-phlebitic varix and ulcer are difficult and show a far lower proportion of cures than those performed for the simple type of surface varicosity.

Acute phlebitis in veins previously normal, such as occurs with typhoid and after childbirth, should be conservatively treated. Convalescence should be prolonged and restoration to active life slow.

Acute phlebitis affecting veins already varicose should be treated by excision.

PRESENTATION OF A BAS-RELIEF OF PROFESSOR D'ESPINE TO THE BOSTON MEDICAL LIBRARY.

On May 1, 1922, a letter was received by Dr. John W. Farlow, Librarian of the Boston Medical Library, from Dr. Charles G. Cumston, formerly of Boston, but now for a number of years Lecturer on Medical History at the University of Geneva, Switzerland, containing the following: "I am sending in your care a replica of the bas-relief of Prof. D'Espine struck on the occasion of his retirement from the University of Geneva, having attained the age limit of seventy-five years. Only forty replicas were made for his former students and friends. This replica I offer to the Boston Medical Library, and if you have no objection, I should like to have Dr. John L. Morse present it in my name, simply because he is conversant with Dr. D'Espine's work and would be able to make some interesting remarks in this respect."

The bas-relief, of which an illustration is here given, was presented to the Boston Medical Library on May 15, 1922, by Dr. Morse, who gave

the following sketch of the medical career of Dr. D'Espine:

"Dr. Cumston has kindly asked me to present to the Library this replica of the bas-relief of Professor Adolphe D'Espine, which was struck on the occasion of his retirement from the University of Geneva at the age of seventy-five years. Jean-Henri Adolphe D'Espine was born in Geneva, February 20, 1846, and studied medicine in Paris, where he took his medical degree in 1873. The title of his Inaugural Dissertation was 'A Contribution to the Study of Puerperal Septicæmia.' He was elected Professor of Internal Pathology at the University of Geneva in 1876, and later was made Professor of the Diseases of Children, both of which positions he held until his retirement in 1921. He is a corresponding member of the Paris Academy of Medicine, the Academy of Medicine of Turin and also that of St. Petersburg.

"In spite of, or perhaps because of, his pathological affiliations, he early became interested in children and their diseases, as is shown by the fact that in 1877 he published with Prof. Picot a 'Manual of the Diseases of Childhood,' which was for many years one of the standard books on children's diseases, not only in Switzerland and France, but also throughout Europe; it was translated into German, Spanish and Greek, and in 1885 was crowned by the Academy of Medicine of Paris. The last edition appeared in 1899.

"Professor D'Espine has always been an investigator and a leader in the advance in our knowledge of children and their diseases and has contributed many articles to medical journals, among the most noteworthy of which are those dealing with cirrhosis of the liver in children, diphtheria and scarlet fever. He is probably best known in this country because of the 'sign' which bears his name. This 'sign,' to which he first called attention in the fourth edition of his 'Manual' in 1889, is a whispering sound heard after the spoken voice over the spinous processes of the vertebrae. The term 'D'Espine's sign' has been applied to many other sounds heard in this region, but it is this whispering sound after the spoken voice which D'Espine described as his 'sign,' and for which he claimed priority.

"Although Prof. D'Espine was retired on account of having reached the age limit of seventy-five years, he is, I am informed by a number of people who have seen him within a year, very alert for a man of his age and mentally as sound as most men of fifty.

"I am sure that the Library will join me in thanking Dr. Cumston for his generous gift and in sending our best wishes to Prof. D'Espine for many years of activity in his chosen field."

In concluding, Dr. Morse presented to the Li-

brary an autograph letter written to him by Prof. D'Espine in 1921 containing references to the "sign" and its meaning. This letter, of which portions are here given in translation, which were preserved with the replica, at Dr. Morse's request.

Professor D'Espine writes: The description of the "sign" which I gave, and which is still accurate today, is contained in the *Bulletin de l'Académie de Médecine*, Paris, 1907, vol. 57, page 167. Another important communication, entitled "Note on the diagnosis of simple bronchial adenopathy in acute and subacute affections of the chest in children" appeared in the same journal for July 23, 1907. To establish the fact that the "D'Espine sign" is due to tuberculosis of the bronchial glands (which is generally the case), there should be the positive skin-reaction after the use of Koch's Tuberculin. This is almost always present when the "sign" has persisted for more than six months.

I may mention an article on the same subject by Dr. Ethan Allen Gray, of Chicago, in the *Transactions of the Fourth Annual Meeting of the National Association for the Study and Prevention of Tuberculosis*. And in the *Schweizerische medizinische Wochenschrift* for June 30, 1921, there is an illustrated article on the "D'Espine sign" by Dr. Th. Reit, with a very complete and up-to-date bibliography of the subject.

After the remarks of Dr. Morse, the different editions of the Manual of Dr. D'Espine and Dr. Picot were shown and also the periodicals containing the references mentioned in the letter to Dr. Morse. These books and journals and the bas-relief are all in the Boston Medical Library, where they can be examined by any one interested in the work of Prof. D'Espine. The fifth edition of the Manual in the Library is a presentation copy from the author to Dr. Cumston and the second edition was a present from Dr. T. B. Curtis, and is inscribed "With thanks and cordial friendship of your old chess-partner, Ad. D'E. Geneva, 27 Oct., 1879."

The bas-relief and the autograph letter were received with thanks by the Medical Library through its Executive Committee, and the Librarian was requested to convey to Dr. Cumston the gratitude of the Library for his generous gift.

SUBSCRIPTION TERMS: \$6.00 per year in advance, postage paid for the United States, \$7.50 per year for all foreign countries belonging to the Postal Union.

Material for early publication should be received not later than noon on Saturday. Orders for reprints must be sent to the printer with galley proof of paper. Upon written request, authors will be furnished free one hundred eight-page reprints, without covers, or the equivalent in pages in articles of greater length.

The Journal does not hold itself responsible for statements made by any contributor.

Communications should be addressed to The Boston Medical and Surgical Journal, 126 Massachusetts Ave., Boston, Mass.

THE ELECTRONIC REACTIONS OF ABRAMS.

WHEN the Greeks placed their wooden horse before the walls of Troy, the Trojans marvelled at it as one of the wonders of the age, and accepted it, vastly to their discomfiture. When Dr. Albert Abrams, of San Francisco, announced that he had discovered a method of diagnosing disease by means of the electronic reactions of the body, he soon gathered about him a number of credulous individuals, mostly osteopaths, who accepted his doctrines and hailed him as "the greatest of all medical men."¹

These 300 or more² disciples of Abrams, scattered throughout the country, have organized classes in which, for a fee of two hundred dollars per pupil, they teach this method to others. *Pearson's Magazine* (June and July, 1922), has declared itself an ardent champion of this "revolutionary discovery," and, fortified by an article by Upton Sinclair, is prepared to force it down the throat of the medical profession.

This propaganda, written up in a sensational way and very cleverly interlarded with a few scientific and many pseudo-scientific facts, is bound to appeal to the less discriminating type of reader, especially if he suffers from some chronic ailment. The JOURNAL feels that the matter is of sufficient importance to be presented briefly but accurately, together with as much

comment as space will allow upon the probable correctness of the Abrams hypothesis.

The essence of the theory lies in the belief propounded by Abrams "that all material things are radio-active and that if sufficiently delicate apparatus can be devised, the degree of radio-activity of all matter can be measured in such a way that when its radio-active characteristics are ascertained, it would be possible from this data to determine the actual substance being examined, without ever seeing it."³

The radio-activity of the individual is manifested by his person, by a few hairs, by several drops of blood, or even by his handwriting! From the last, information can be gained as to the age, sex, approximate height and weight, condition of health and nationality of the writer. Even the nationality of his parents may be so determined. The radiations from an individual's handwriting pass toward him, if he is alive; if he is dead, his writing no longer "vibrates in resonance with him."⁴ This fact, however, does not prevent Abrams from ascertaining from the writing of persons long since deceased the nationality and the state of health of the writer. Dr. Samuel Johnson suffered from acquired syphilis (cerebro-spinal) and tuberculosis; Samuel Pepys, Edgar Allen Poe, Bret Harte and Henry Wadsworth Longfellow all had congenital lues.⁵

Not only the living body, but even bits of tissue hardened in 4% formalin, give the characteristic reaction for the disease which is present. Unfortunately the only diseases recognized thus far are carcinoma, sarcoma, tuberculousis, syphilis, colicsepsis and streptococemia.

The radio-activity which yields this information can be detected only by means of the reactions which it arouses in a human subject. These reactions consist in an increase in vascularity of certain abdominal organs; this manifests itself by increased dullness upon percussion over these organs, or by increased friction when a glass or rubber wand is rubbed across the overlying areas. We return to the original source for a description of the technic employed in eliciting these reactions.⁶

"Let us enter a laboratory where diagnosis is being made by electronic methods. In the subdued light, we see a young man stripped to the waist and the diagnostician is percussing various areas of his abdomen and carefully noting the variation in percussion sounds. This young man is called the 'subject' (or re-agent) and is facing the geographical west, which has previously been carefully determined by means of the compass."⁷

"Beside the living human 'subject', the apparatus required is as follows:—The 'Dynamizer', which is merely a specialized type of condenser and consists of a little round black wooden box containing metallic contact points

from which grounding wires run to the water pipes or radiator. From the metallic top of this condenser passes a short insulated wire to the 'Reflexophone,' which is simply a specialized type of triple rheostat, capable of measuring up to a total of 61 Ohms. From this rheostat passes another insulated wire having on its free end a small aluminum electrode which is applied to the forehead of the young man being used as the 'subject.'

"Here, then, is the complete apparatus required for making our electronic diagnostic reactions; the Condenser (or Dynamizer), the Rheostat (or Reflexophone), and the automatic reflex nervous mechanism of the living human 'subject.' (Dogs and other animals have also been used experimentally and have given good results in this work.)

"PRACTICAL TESTS.

"Let us conduct an experiment with a piece of cancer tissue preserved in formalin solution in a small bottle. This bottle is placed in the Condenser and the Rheostat is set at 50, which has been shown to be the vibratory rate for carcinoma. It would be entirely immaterial whether actual cancer tissue were being used or some blood from a patient having carcinoma—the reaction would be the same, because the blood itself would tell precisely the same story as the cancer tissue.

"Previous to the experiment, the abdomen of this young man has been percussed all over, in order to determine his normal degree of resonance for that particular time.

"After the electrode from the Rheostat has been placed upon his forehead, the lapse of fifteen or more seconds is required, after which careful percussion will note a beginning dullness in an area about two finger-breadths in height and extending for perhaps six or eight inches across his abdomen at the level of the umbilicus. This particular area will soon become very noticeably dull upon percussion, and if the electrode be then removed from his forehead, the dullness will within a few seconds be replaced by the previous resonance. This test can be repeatedly made and will always give the same definite reaction upon the specified area of our 'subject's' abdomen.

"Many physicians find difficulty in differentiating between the delicate shades of pitch and tone when using percussion, and it is, therefore, fortunate that a way has been found whereby they may secure their electronic reactions by other means. During some of his constant laboratory experimenting Dr. Abrams found, by the use of a pith-ball charged with static electricity, that the area of his 'subject's' abdomen which was dull upon percussion was also throwing off more energy than the surrounding tissues, due to the increased vascularity of the underlying organs. The outcome of this simple discovery was perfectly logical, as, indeed, is every other step of the entire procedure when its fundamental

principles are intelligently understood. He found that if a glass rod or rubber wand, properly charged with static electricity by brisk rubbing with silk or wool, were swept over the 'subject's' abdomen, it would become noticeably retarded in its progress across that particular area which was dull upon percussion—all other areas being perfectly smooth. It has been found by prolonged demonstration that the glass rod or rubber wand method is fully as accurate as the percussion method, and may even be used at times for even more delicate reactions."

Once the diagnosis is established, the disease can be checked by imposing upon it its own "vibratory rate." This is done by means of a machine called the "oscilloclast."

The treatment of certain diseases by means of particular drugs has been successful because those drugs have possessed the same vibratory rate as the disease itself. It is not claimed for electronic therapy that it will restore damaged tissues to a normal condition. All that it does is to deprive the disease of its vitality. A cancer, for example, loses its malignancy when so treated.

The cleverness of the above outlined theory lies in its immunity from attack. It is so indefinite that you cannot get at it. A thorough physicist realizes its fundamental absurdities. If, however, he objects to Abrams' contention that "all material things are radio-active" Abrams replies that they may not be radio-active by ordinary standards, but when measured by his vastly more delicate tests they prove to be so.

As a matter of fact, radio-activity is as definite an attribute as fluidity. A radio-active substance sends out either corpuscular radiation (alpha or beta rays) or electro-magnetic radiation (heat, light, x-rays or gamma rays). These radiations exert perfectly well-known influences upon their surroundings. In no case do they exert influences which could be conducted along a wire as described by Abrams. If the little box which he describes as the Dynamizer were a condenser, the radiations could cause a leak of electricity between the plates of the condenser, providing a difference of potential is maintained between these plates. The only variation of this leak which we could recognize would be a change in the amount of current. Abrams' apparatus is not adequate to make such measurements.

It is a physical impossibility for such a device to transmit anything correlated with the "vibration frequency" of the electromagnetic radiations (if there be such); the corpuscular radiations do not have the attributes of vibration frequency.

Let us assume for the moment, however, that some vibratory rate is communicated to the subject.

This vibration is alleged to produce definite, constant areas of vasodilation within the abdo-

men. The areas over which dullness is supposed to appear correspond with no anatomical vascular units. What organ or combination of organs, for example, can give the carcinoma dullness—"An area about two finger-breadths in height and extending for perhaps six or eight inches across his abdomen at the level of the umbilicus"?²

The "reading" of the reaction by Abrams' methods of percussion or stroking with a wand is absurdly inexact. Percussion is never an accurate method of examination, for the force of the blow is not constant. The abdomen, furthermore, is a cavity in which, owing to intestinal peristalsis, areas of dullness are constantly changing. The degree of resistance encountered in stroking the skin with a glass or rubber wand is an even less reliable indicator; the friction developed depends upon the moisture of the skin, upon the muscular effort put forth in holding the rod against the skin, and upon the protrusion or retraction of the abdomen caused by the respiration. By means of these extremely coarse methods, a reaction admittedly too delicate to be measured by the finest instruments yet devised by man, is read not only qualitatively but quantitatively.

The application of the electronic reaction to the cure of disease is completely at variance with the modern theories (Twentieth Century or Einstein's Theory) of radiation, and is not in accordance with the experimentally established facts of absorption and emission of radiation.

It may be that Dr. Abrams knows of some method of research which makes unnecessary the laborious yet nevertheless definite experiments of other physicists. In the presentation of his theory he does not describe the fundamental experiments upon which so momentous a discovery as his should be based. In regard to the results of the clinical application of his theory he again rejects that method of scientifically controlled experimentation which, up to now, has been demanded of those who would establish new theories in the world of science. Abrams was offered a ward in a San Francisco hospital for the scientific demonstration of his methods, but he refused the opportunity.

Yet, free as it is from any true scientific basis, Abrams' theory, upon superficial acquaintance, has a distinct appeal. Its proponents take advantage of the recent popular interest in Radio, and impress the reader by the free use of such terms as "vibrations," "wave-lengths" and "electrons." Many of the alleged "cures" have been performed upon a pathological condition demonstrable by no other method. Relief of symptoms can, in many instances, be attributed to coincidence or to the power of suggestion wielded by such a novel method of treatment.

The outstanding fact is this: the Electronic Theory of Abrams, in its fundamental concep-

tion, is directly opposed to many of the experimentally established laws of modern science; it cannot be accepted unless one is ready to cast aside all of the accumulated evidence of physics and mathematics in favor of a naked hypothesis unsupported by a single basic experiment.

ANTIVACCINATION LECTURE BY RADIO

In the *Christian Science Monitor*, under date of July 29, 1922, there is the report of the lecture by Henry D. Nunn, manager and general counsel of the Medical Liberty League, sent broadcast by radio from Medford Hillside, Mass. In this message it is asserted "that the percentage of fatalities of smallpox epidemics has been greatly increased in the Philippines, where vaccination is preëminently extensive and that a similar tendency is observed in Japan." Further, it is claimed that vaccination is questioned by a large proportion of thinking people and that the great majority of those who believe in vaccination, including most physicians, take vaccination purely on faith without giving the subject any real thought.

He then propounds such questions as "what is vaccination" and "is vaccination harmless or dangerous." He states that there were 10,000-000 vaccinations performed in the Philippines from 1905 to 1910, yet in 1918, 1919 and 1920 there were 162,000 cases of smallpox, of which 71,000 were fatal. During this latter period of three years he states that there were 15,600,000 vaccinations, but that smallpox is becoming more deadly in that country. He says that in the 20-year period ending in 1908 there were in Japan 288,000 cases of smallpox, of which 77,000 were fatal. He then goes on to say that among our soldiers in the Philippines from 1898 to 1920 there were 737 cases of smallpox, with a mortality of 261.

This lecturer evidently feels that his most telling argument lies in the fact that some persons who have been vaccinated have developed smallpox, but he neglects to state that in the few instances where smallpox has developed in persons who have had effective vaccination there are, as a rule, no deaths.

He states that smallpox virus is used to produce vaccine matter in this state through cultivation in the calf. He neglects to state, however, that the smallpox virus is only used to produce the initial inoculation of the calf and the vaccine finally applied to human beings is the end-product of successive inoculations for

a period of not less than five years, which is an explanation quite logical to well-informed physicians. He ignores the statements of Heiser in the *Journal of the A. M. A.*, July 1, 1922, and the letter to this *JOURNAL*, by Major-General Leonard Wood, explaining the situation in the Philippines, and omits the great illustration of the record of vaccination in Manila, where smallpox was completely stamped out under the administration of this Government. The subsequent development of smallpox is perfectly well explained by the facts, for vaccination was for a period paid for at a per capita rate and the operators were more inclined to secure income than to perform vaccination. That a great deal of impotent vaccine has been used in the Philippines is undoubtedly true.

Our physicians will relish the coarse humor of the statement that physicians have not given the subject real thought. The statement is controverted with all modesty, but we can claim that Major-General Wood and Dr. Heiser are thinking men. Dr. Heiser is now in the Philippines and we shall soon have a different story.

The State Department of Health is in possession of much material on the whole subject which will probably be put before the public at an opportune time. For the comfort of our citizens it may be stated that no valid complaint has been made of the quality of virus prepared in this state during the past five years, although successful results may not follow in those cases where the arm has been treated with potent antiseptic washes.

A strong argument in favor of vaccination appears in the Statistical Bulletin of the Metropolitan Life Insurance Company for July, 1922. This great organization studies the problems of life and death in a scientific spirit for the purpose of applying knowledge to the business of life insurance. If it could be found that vaccination maims and kills and does not prevent smallpox, or, further, if vaccination conveys syphilis, this company would ally itself with those who are opposed to vaccination. The following quotation from the Bulletin shows the attitude of the company.

"Students of the prevailing worldwide menace of smallpox have seen many statements from anti-vaccination propagandists that the sad experience of the Philippines in 1918 and 1919 was a repudiation of the principals of modern public health measures for smallpox suppression. These statements are mere allegations that 50,000 smallpox deaths occurred in the face of systematic, persistent vaccination. The real truth is that the practice of effective vaccination had been exceedingly lax since the general campaign of 1909 or thereabouts and that most of the 50,000 deaths occurred among the children and other elements of the population unprotected by the indifferent pursuit of vaccination in recent years in the Islands. The age statistics given by Drs. Heiser and Leach for Pangasinan

and for Manila show a predominance of both cases and deaths among the unvaccinated. A careful review of these facts will make it possible for American health officers to refute the diligently circulated misstatements of the anti-vaccinationists."

PHYSICIANS IN CONGRESS.

It is an interesting fact that physicians as a class are not often inclined to seek political office. There are five hundred and thirty-one members of both houses of Congress, but only eight physicians are found among them, although one other has an honorary degree of M.D., as shown by the report of the National Health Council. An examination of the Congressional Directory shows the following named doctors of medicine: Senators, Lewis Heiser Ball of Delaware, M.D., from the University of Pennsylvania, 1885; Joseph Irwin France of Maryland, M.D., from the College of Physicians and Surgeons, Baltimore, fellow of A. M. A.; Sheldon Palmer Spencer of Missouri, although a lawyer, has an honorary M.D. from Missouri Medical College, because he lectured on Medical Jurisprudence.

Representatives: John Joseph Kindred of New York, M.D. from Hospital College of Medicine, Louisville, Ky., also record of study in post graduate work at University of N. Y. and University of Edinburgh, graduating from the department of mental disease of the latter. He is also an LL.B.; Caleb R. Layton of Delaware, M.D. from University of Pennsylvania; Ladislav Lazaro of Louisiana, M.D. from St. Isadore's College, New Orleans; Archibald E. Olpp of New Jersey, M.D. from University of Pennsylvania; John William Summers of Washington, M.D. from Kentucky School of Medicine and Louisville Medical College, with post-graduate studies in New York, London, Berlin and Vienna; Lester D. Volk of New York, M.D. from Long Island Medical College, formerly editor of the *Medical Economist*. He is also a lawyer and has devoted himself to law since 1913.

Dentistry is represented by Representative Roy C. Woodruff of Michigan, Doctor of Dental Surgery, Detroit College of Medicine. Pharmacy by George W. Edmonds of Pennsylvania, a graduate of the Philadelphia College of Pharmacy; and Public Health by R. S. Malony of Massachusetts, who was formerly director of public health in Lawrence, Mass.

Lawyers make up the great majority of the members of both branches.

Considering the training and work of physicians, it is not surprising that few care to enter the arena of political contests. Physicians are aggressive in combating disease, but few enjoy that kind of controversy which is a feature of campaign debates; but whenever a well informed

physician becomes a member of a body that deals with the various problems of preventive medicine, his experience is of the greatest value to the state, and in many other departments of state activities he is better qualified than most men to appreciate meritorious measures and detect unworthy or dangerous motives. It is becoming more evident in these later days that one of the great concerns of the state lies in the mental and physical well being of its citizens, and a large percentage of physicians in legislative bodies would help in advancing sound laws and rejecting unworthy proposals. Massachusetts has been indebted in the past to a comparatively few physicians who have sacrificed financial interests in taking on legislative responsibilities. There will probably be others who will take up this work in the future, but there is little hope that the numbers will be large enough to have any commanding influence in Congress or in state legislatures.

NEWS ITEMS.

CHANGES IN THE FACULTY AT HARVARD.—Dr. Edward P. Richardson has been appointed assistant professor of surgery at the Medical School of Harvard University, Boston. Dr. Reginald Fitz, for the last two years professor of medicine, University of Minnesota, has been named associate professor of medicine. Leonard T. Troland, for six years instructor in psychology, has been promoted to an assistant professorship. Dr. Jacques Bronfenbrenner has been appointed assistant professor of bacteriology; Dr. Alice Hamilton, assistant professor of industrial medicine; Dr. George Shattuck, assistant professor of tropical medicine; Dr. David Cheever, assistant professor of surgery; Dr. Lloyd D. Felton, assistant professor of preventive medicine and hygiene, and Dr. James L. Gamble, assistant professor of pediatrics. Dr. James S. Stone and Dr. John Homans have been appointed instructors in surgery, and Drs. William H. Smith and Frank H. Hunt, instructors in medicine.—*Journal A. M. A.*, August 5, 1922.

WEEK'S DEATH RATE IN BOSTON.—During the week ending August 5 the number of deaths reported was 169 against 158 last year, with a rate of 11.54. There were 20 deaths under one year of age against 28 last year. The number of cases of principal reportable diseases were: diphtheria, 15; scarlet fever, 8; measles, 40; whooping cough, 41; typhoid fever, 2; tuberculosis, 22. Included in the above, were the following cases of non-residents: diphtheria, 1; scarlet fever, 2; tuberculosis, 2. Total deaths from these diseases were: scarlet fever, 1; measles, 2; typhoid fever, 2; tuberculosis, 13. Included in the above, were the following cases of non-residents: tuberculosis, 2.

DR. SHEPPARD APPEALS.—Dr. Philip A. E. Sheppard, through his attorney, has appealed to the Supreme Court, asking that the action of the Board of Registration in Medicine in revoking his certificate as a registered physician be reviewed and set aside.

MALPRACTICE SUITS IN IOWA.—The Iowa State Medical Society reports that attorneys' fees for medical defense of its members amounted to \$4,914.94 for the previous year and that twenty-six cases are now pending.

Miscellany.

MEDICAL RESEARCH IN AMERICA.

DR. W. S. LAZARUS BARLOW, Professor of Experimental Pathology at the Middlesex Hospital of the University of London, who has been visiting the medical centers in this country, has stated that the resources for medical progress in America exceed those of any other country, especially along research lines. He explains this in referring to the wealth of the United States, together with extraordinary facilities. With justifiable loyalty to his own country he says that "We in England have the men, but we have not the facilities," and further raises the question as to the ability of Americans to develop men of a type equal to those of the older country. If such men can be found in America he concedes the probability of the greatest possible progress in medical research. He explains his meaning in allusion to facilities by referring to the Crocker Institute for Cancer Research, the Rockefeller Foundation and our supremacy in the amount of available radium.

We trust that we, as a nation, are as modest as any other, but we may be pardoned for believing that in addition to the facilities we are developing the kind of men who will carry on the highest type of research work.

THE LEGAL OWNERSHIP OF A STILL.

IN advertisements the dealers in stills recommend the purchase of these utensils for the purpose of distilling water, with the claim that distilled water is valuable in the treatment of some diseases or may be useful in eliminating the danger of water-borne diseases.

In order that physicians may know the law the following letter is published.

Treasury Department, Internal Revenue Service, Boston, Mass.

Mr. Editor:

Your letter of July 31st received, Section 18, Title 2 of the National Prohibition Act reads as follows:

"It shall be unlawful to advertise, manufacture, sell, or possess for sale any utensil, con-

trivance, machine, preparation, compound, tablet, substance, formula direction, or recipe advertised, designed, or intended for use in the unlawful manufacture of intoxicating liquor."

However, stills not intended for use in the production of Distilled Spirits may be legally purchased and possessed providing the purchaser of the still shall register the still with the Collector of Internal Revenue on certain forms prescribed. The procedure for the legal purchase and possession of a still is as follows.

The prospective buyer furnishes the vendor with affidavit in triplicate to the effect that the still he intends to purchase is not to be used for Distilled Spirits, but is to be used for some other purpose specified. The vendor then requests permission in writing, to which is attached one copy of the affidavit, from the Collector of Internal Revenue for the District in which he is located, to remove the still to the prospective buyer, which permission is granted. The Collector's Office then notifies the purchaser that he should register still on forms 26, which are furnished him. This completes the Federal requirements for the purchase and registry of a still.

Respectfully,

Malcolm E. Nichols,
Collector.

WISCONSIN BARS OUT FILLED MILK.

By legislation and court decisions the people are winning the fight against all so-called milk compounds. The decision in Wisconsin Supreme Court, July 20, in the now celebrated "Hebe" case brought by the Carnation Milk Products Company and the Hebe Company, upheld the state law forbidding the manufacture and sale of the compounds of skimmed milk and vegetable oil. The Carnation Milk Products Company, plaintiffs in the case, had sought to enjoin J. Q. Emery, dairy and food commissioner, from enforcing the law as against their product known as "Hebe."

This much advertised compound, which the Court found to be similar in taste, odor, appearance, consistency and manner of packing to evaporated milk, has been manufactured by the Carnation Company and sold to its subsidiary, The Hebe Company, for five years. It has been advertised by certain dealers in the newspapers of Wisconsin as "milk" or "compound of milk"; and has been sold by a number of retailers in Wisconsin as "milk" or "evaporated milk."

This and other compounds are shipped out of the state and advertised and sold by many dealers in other states as substitutes for milk. Labels on the cans of some of the compounds suggest that this product is practically equivalent to or better than genuine evaporated milk.

The supreme court based the right of Wis-

consin to outlaw "Hebe" and other milk compounds on the police power of the state, and declared the law valid for three reasons:

1. Because the law is intended to prevent fraud and deception.
2. Because it protects public health and welfare.
3. Because it promotes the general prosperity by preserving a great industry of the state.

Justice Charles H. Crownhart, who wrote the decision and the accompanying statement of fact, pointed out that the history of legislation relating to filled milk was most persuasive. "It will be seen," said he, "that the compounds have been considered inimical to public welfare by a large portion of the people of this country."

He pointed out that thirty-three states had adopted standards for condensed or evaporated milk; that the manufacture and sale of filled milk had been absolutely prohibited in New Jersey, New York and Wisconsin; that five other states had prescribed standards for condensed or evaporated milk that in effect prohibit filled milk; and that three states had passed laws which permit filled milk to be sold as "imitation milk."

LIFE TABLES FOR STATES AND CITIES. 1920.

The Department of Commerce, Washington, announces that abridged life tables based upon the 1920 United States Census will soon be issued showing conditions in 24 states and 14 large cities, also in the territory of Hawaii.

Altogether these tables cover 74 per cent. of the total population of the United States. They show for these states and cities taken as an aggregate, that the expectation of life at birth is 55.23 for white males and 57.41 for white females.

According to these tables the longest lived people in the United States are the Kansans, the expectation of life at birth in Kansas being 59.73 for white males and 60.89 for white females. Wisconsin ranks next with 58.77 years for white males and 60.70 for white females. If a record as a standard of comparison be desired it may be found in the figures for females in the county of West Sussex, England, whose expectation of life, the highest ever published officially by any country, was 63.05 in 1911-12.

Washington, D. C., outranks all other of the 14 cities with 53.83 years as the expectation of life for white males and 59.83 for white females. Pittsburgh comes at the foot of the list with 47.16 years for white males and 50.42 for white females.

For Negro males in the large cities the expectation of life is 37.92 as compared with 51.55 for white males, a difference of 13.63 years. For

Negro females the figure is 40.28 and for white females, 51.77.

For purposes of comparison and to indicate progress, a table is included covering the census years 1910 and 1920. This, however, is restricted to the "original registration states" which include the six New England States and also New York, New Jersey, Indiana, Michigan, and the District of Columbia, since figures for other states are not available as far back as 1910. Within this area the expectation of life for white males has advanced from 50.23 in 1910 to 53.98 in 1920, an increase of 3.75; and for females it has advanced from 53.62 to 56.33, an increase of 2.71.

EXPECTATION OF LIFE
Original Registration States

Year	Sex	Age 0	Age 32	Age 62
WHITE				
1920	Males	53.98	34.93	13.38
1910	Males	50.23	33.33	12.85
	Difference	3.75	1.60	.53
1920	Females	56.33	36.12	14.01
1910	Females	53.62	35.40	13.70
	Difference	2.71	.72	.31
NEGRO				
1920	Males	40.14	28.50	11.42
1910	Males	34.05	25.16	10.88
	Difference	6.09	3.34	.54
1920	Females	42.16	28.82	12.12
1910	Females	37.67	28.33	11.96
	Difference	4.49	.49	.16

For those males who have reached the age of 32 the expectation of life is 34.93 years, and for those who have reached the age of 62, it is 13.38. For white females it is 36.12 at the age of 32, and 14.01 at the age of 62. These life tables show a marked improvement in mortality conditions among all classes between 1910 and 1920, except at certain ages between 17 and 32, these exceptions being due to the influenza epidemic.

While the various mortality conditions show that the chances of living are much more favorable among whites than among Negroes, the improvement among Negroes between 1910 and 1920 was slightly greater than among whites. Had it not been for the influenza epidemics of 1919 and 1920 the expectation of life shown for 1920 would have been considerably greater for both whites and Negroes.

AFTER-EFFECTS OF WARFARE GASES AND THEIR RELATION TO TUBER- CULOSIS.

Lieutenant Colonel H. L. Gilchrist, Medical Corps, U. S. A., has made a careful study of this subject and has prepared a report setting forth his conclusions.

The object of the dissemination of his opinions appears to be a desire to relieve the minds

of victims of gas poisoning of the impression that such persons are liable to develop tuberculosis for "large numbers of ex-soldiers are laboring under constant mental worry fearing" the development of tuberculosis. He endorses the opinion of Dr. John B. Hawes, Jr., who has emphasized the following points:

1st.—That it must not be taken for granted that a given process is tuberculosis, even with a suggestive x-ray;

2nd.—That the general appearance of robust health with marked symptoms, is against tuberculosis;

3rd.—That lung complications resulting from gas are usually basal and not apical processes;

and quotes from the report of Dr. James A. Miller, as published in the American Review of Tuberculosis, Vol. III, page 51, as follows: "There seems clear evidence that tuberculosis has not increased by the influence of the late war upon the armies and if anything, it has diminished the hazard of pulmonary tuberculosis, reports from France, Great Britain, Belgium and United States, all showing great decrease in tuberculosis during the later periods of the war.

His conclusions are given as follows:

1st.—That a large number of individuals were undoubtedly sub-standard in the beginning and would quite probably have broken down under any stress or strain.

2nd.—That the generally unknown effect of warfare gases has furnished many individuals a peg upon which to hang all manner of symptoms.

3rd.—That the period of time between our entry into the war and the present date, has offered ample opportunity for the onset of diseases totally unassociated with war wounds or exposure.

4th.—As to the incidence of pulmonary tuberculosis resulting from exposure to gas, it would seem that it is far from convincing that gas played any particular rôle in this connection and it is doubtful if the incidence of lung tuberculosis among ex-service men is much greater by reason of the part that gas played.

5th.—Those who claim to have developed tuberculosis a year after leaving the service, from conditions experienced in the Army, certainly have no basis for such assertion. They probably would have become tuberculosis patients even if they had never been in the Army.

6th.—There are two elements entering into this problem—one neurasthenia, where the men were gassed, usually very slightly, and believed sincerely that this was a factor in their illness; and second, mistaken diagnosis in many cases, especially those following influenza, in which, instances of unresolved broncho-pneumonia occurred, leaving nodular patches upon which the diagnosis of tuberculosis was frequently based on x-ray plates.

These opinions should furnish much encouragement to ex-soldiers and physicians.

BABY HYGIENE ASSOCIATION.

The report of this organization for ten months of the year ending December 31, has been distributed.

Twenty-two welfare stations are maintained where instruction in proper feeding, care, and hygiene of infants and children is given. Visits to homes by nurses and dietitians are made and cooperation with public health authorities and social agencies on matters pertaining to child welfare is carried on.

The statistics are of great interest:

There were 15,894 infants and children cared for and 142,139 home visits made.

The infant mortality rate among those cared for has been reduced from 17.87 in 1920 per 1000 to 12.54 in 1921.

The city infant mortality rate for 1921 is 77.85. Financial pressure necessitated the reduction of the nursing force in the autumn.

The receipts for the year amounted to \$72,760.54 and the expenditures, \$74,583.26.

The report should be read by every physician, health officer, and social worker. The results obtained should be common knowledge. This organization shows how lives can be saved and health maintained among infants and children. The comparison of the mortality rate among those cared for by this association and the average rate among other infants and children places a definite responsibility upon municipalities. If health is purchasable, as has been claimed, society at large may be regarded as responsible for a large proportion of deaths among infants and children. This organization shows results which should make us ashamed of the average infant mortality rate.

INSTRUCTIVE DISTRICT NURSING ASSOCIATION.

MONTHLY HEALTH BULLETIN FOR AUGUST, 1922.

There were 163,684 visits made to 23,351 patients during the first 6 months of 1922, an increase of 15,756 visits and 2,655 patients during the same period last year. The increase occurred principally during the first three months, when there was an undue prevalence of acute illness.

Nursing visits increased by 19,078, while fewer purely preventive visits were made.

ACUTE AND COMMUNICABLE DISEASES.

Acute and communicable diseases this year jumped to 58% of the whole, from 38% of the entire work in the first half of 1921. This was a proportion encouragingly suggestive that the vital nursing needs of the community are being served. Influenza, pneumonia and other respi-

tory diseases are, of course, responsible for a large proportion of the increase, which, however, was also shown in some of the other diseases. There were 664 cases of measles as against 377 last year; erysipelas 90, against 46; a slight increase in diseases of the digestive system; 546 cases of burns, traumatism, fractures and sprains, against 403; also an increase in the diseases of the eye and ear. There were fewer cases of typhoid fever, whooping cough, chicken-pox and mumps.

CHRONIC DISEASES

There was a slight decrease in the proportion of chronic diseases, these being only 11% of the entire work. In opposition to the general decrease, cancer stood out, with 161 cases against 121 of last year.

MATERNITY.

Of the work, 24% was maternity work.

The results compare favorably with those of last year, the maternal death rate being 2.75 per 1,000; while the stillbirth rate for the prenatal cases dropped from 30 to 28.8 per 1,000 births.

The infant death rate under two weeks (prenatal cases) was 24.4 per 1,000, somewhat higher than last year.

There was a rather marked drop in the number of prenatal cases cared for, —purely preventive work,—2,695 this year, against 3,009 last.

There were 311 deliveries attended, 38 more than in the first six months of 1921.

BABY HEALTH WORK.

There were 1162 babies registered at the three Baby Health Clinics, a slight increase over last year. There was also a good increase in attendance at all these clinics.

The death rate was 15.1 per 1,000 babies under 1 year, a rate very much higher than last year, and one which accords with a general tendency throughout the country toward increased infant mortality.

No baby died of a digestive disease, while 5 babies died of pneumonia and 5 others who died were in a poor physical condition at birth.

CHILD HEALTH WORK

There were 469 children registered at the Child Health Clinic. Nine of the new children were found in perfect condition, the others averaging 2 defects.

Of the children who had diseased tonsils and adenoids, 58% were operated upon in hospitals and dispensaries.

Of the children with defective teeth, 58% were cared for, the majority of them at the Dental Clinic in the Hyde Park Health Center.

There were 15 nutrition clinics held in the Health Center for children found in the Health Clinic to be 7% or more under weight.

INCORPORATION OF THE AMERICAN SOCIETY FOR THE CONTROL OF CANCER.

THE following circular of information appears in the *Campaign Notes* of this society for July, 1922:

"On May 15, 1922, the society was incorporated under the membership corporations law of the State of New York. This step was taken after the judiciary committee of the Senate had decided against recommending the incorporation by special act of Congress of the charitable, benevolent and educational organizations, including this society, which had applied for national charters.

"The certificate of incorporation of the society states that 'its operations are to be principally conducted in the United States of America' and describes its purposes as follows:

"To collect, collate and disseminate information concerning the symptoms, diagnosis, treatment and prevention of cancer; to investigate the conditions under which cancer is found, and to compile statistics in regard thereto."

"The plan of organization of the society is now—

"1. A board of directors of five members which will have charge of its financial and legal affairs.

"2. An executive committee of 20 members which will have charge of its general activities and its field work.

"3. An advisory council of not to exceed 100 members which will advise with the board of directors and the executive committee in regard to the activities and management of the society.

"The officers and directors of the society for the first year are:

"Dr. Charles A. Powers, president; Dr. Howard C. Taylor, vice-president and chairman of the executive committee; Calvert Brewer, treasurer; Thomas M. Debevoise, secretary; Elsie C. Mead, chairman of the finance committee.

"The officers of the advisory council for the first year are:

"Dr. Edward Reynolds, chairman; Dr. Clement Cleveland, vice-chairman; Dr. Livingston Farrand, vice-chairman; Dr. George E. Armstrong, vice-chairman; Dr. Rudolph Matas, vice-chairman.

"The society is now in a position to receive the Lasker Fund and other gifts which may be made to it."

The society has ready for distribution a copy of the certificate of incorporation and the by-laws. Under membership several classes are provided for: (a) Donors, who shall give to the society \$5000 each; (b) patrons—who shall pay dues to the society of \$50 per annum; (c) sustaining members—who shall pay dues of \$25 per annum; (d) annual members—who shall pay dues of \$5 per annum.

Any persons who shall contribute \$1 per annum shall, subject to approval of the board of directors, be known as associate members, but without voting privileges.

CURABILITY OF INSANITY.

DR. GENIE-PERRIN, secretary-general of the French League of Mental Hygiene, says that "the social scourge of insanity is both curable and avoidable, and that the asylum remains the tomb of chronic cases and thereby acquires the reputation of an institution at whose doors all hope must be abandoned. . . .

"The condition of a lunatic, from a medical point of view, is the same as was that of a tuberculous subject before the time of Pasteur. . . . Everything now done for tuberculosis can now be done for mental diseases. . . . The early diagnosis and preventive treatment of mental disorders can be and must be a matter for the organization and action of the state. . . .

"Since the psychopath is frequently a victim of self-neglect, and those so predisposed are unaware of the danger which they run, they must be actively confronted, without waiting for them to seek advice. To track down such individuals on their daily round of business, or study and lead them to the clinic, is a work which is already being performed in certain countries—notably in the United States.

"Encouraged by the Board of Mental Hygiene of New York, social psychiatry has been developed in America with the collaboration of large numbers of specially qualified assistants whose efforts have met with much success."

The article in full appears in the *World's Health* for June, 1922.

EXCERPTS FROM THE UROLOGIC AND CUTANEOUS REVIEW.

When it comes to differential diagnosis few of us carry a sufficiently large stock in trade.

Thinning of the outer thirds of the eyebrows should lead one to suspect hypothyroidism.

Remember that an inflamed umbilicus in the adult may harbor the diphtheria bacillus, or the tetanus bacillus.

Do not be thrown off your guard by the trivialness of prickly heat; find out what is the matter with the patient.

A rare case may bring great profit to your pocketbook, but it should bring still greater profit to your stock of knowledge.

If you send your patients away with instructions written out fully, clearly, briefly, you will buy more bonds next year.

Remember that the over-treatment of syphilis may defeat its very purpose by breaking down tissue resistance and immunity.

Objectionable tattoo marks should be excised, or overlaid with a tattoo pattern that will obscure their objectionable character.

Do not forget that a pyoderma of the feet and legs of children may be kept up by flea bites; inquire as to their house pets.

Itching in the midline of the lumbo-sacral region, in the absence of a skin lesion, should lead one to look for an occult spina bifida.

Efficient therapy of an inflamed lesion of the feet may be frustrated if the patient continues to wear cordovan or other poorly ventilated shoes.

For a very waxy seborrhoea of the scalp nothing is better than the cautious use of powdered white precipitate well rubbed into small areas of the scalp every day.

The Wassermann reaction in unskilled hands, like a rifle in the hands of one who does not know how to use it, may unsuspectingly go off in the wrong direction.

Pellucules of dandruff may adhere to hair shafts so as to closely resemble nits; use a lens, and do not embarrass yourself and the patient by improperly diagnosing pediculosis capitis.

In the presence of a difficultly curable disease, protect yourself by never failing to fully describe to the patient the ultimate evolution of the disease, lest he blame the change to alleged improper medication.

Unless you have more than a casual knowledge of radium therapy, all of your patients requiring radium should be placed under the care of a man possessing special knowledge of this element and its use.

Have your syphilitic patients weigh themselves regularly at least once a month. A loss of weight should immediately arouse suspicion of the possibility of over-treatment with mercury, and points plainly to the need of reconstructive treatment.

Do not dismiss a neurotic or timorous patient with the assurance that a lesion is "just nothing"; anything is always something; if the lesion is really negligible, always explain why; you will thereby give the patient his just due, and also protect your reputation from the charge of carelessness.

RED CROSS NOTES.

THE Red Cross has appropriated \$1,500 from its relief fund for the benefit of victims of the Chicopee disaster. Miss Ellen H. Campbell of the Holyoke Chapter is acting as chairman of the relief committee.

Officials of New York city have expressed appreciation of the service rendered by fourteen Red Cross nurses in caring for victims of the West Twelfth Street fire, July 18. Two persons lost their lives and more than thirty were injured. In addition to nursing service a can-

teen was established for assistance of homeless women and children.

Boston Metropolitan Chapter is giving free instruction in life-saving methods at six beaches.

The National Convention will be held in Washington, D. C., Oct. 9, 10 and 11.

A full-time health unit has been established at Rochester, Ind. The Rockefeller Foundation, the county, the city of Rochester, and the State Board of Health will share with the Red Cross and the Tuberculosis Association in financing the service.

Miss Alice Killelea has been appointed executive secretary of the Fitchburg Chapter.

THE SCARLET FEVER GERM.

R. W. PRYER, D.P.H., Detroit, Mich., in an article published in the *Journal of Laboratory and Clinical Medicine*, states his belief that this disease is caused by a spore-bearing organism which shows several varieties, "one of which is, under certain conditions, somewhat similar in its morphology to B. diphtheria and which may be a toxic producer." If subsequent study justifies this belief, a distinct advance has been made in this field, but the reading of the article leads to the fear that the writer may be over-enthusiastic.

MEDICAL WOMEN'S INTERNATIONAL ASSOCIATION.

THE second meeting of the Medical Women's International Association will be held at Geneva, Switzerland, from the 4th to the 7th of September, 1922. All members or prospective members are urged to be present. Each society of medical women throughout the world is invited to send one eligible delegate, and an additional delegate for every 100 members.

Interesting reports will be read by medical women from different countries, and the constitution of the organization will probably be revised in accordance with the provisions under which it was adopted.

Clinics in the different European cities may be visited en route. The attractions of travel in Europe are great this year. Practically all countries are accessible, and the Passion Play will be on at Oberammergau during the entire summer.

OPENING FOR A PHYSICIAN.—Dr. Walter L. Burrage, Secretary of the Society, reports having received information from a resident of Marshfield that a physician might secure a good practice there. Marshfield is an attractive coast town in Plymouth county, with a large summer population.

AMERICAN RELIEF ADMINISTRATION.

Moscow, July 3 (By mail).—Thirty-three physicians and surgeons, each in charge of one of the Moscow hospitals, have united in signing the following letter of thanks to Dr. W. D. Nickelsen, medical supervisor of the Moscow district for the American Relief Administration:

"At the moment when the Moscow city hospitals were insufficiently supplied with food and other necessities for the care and cure of the sick, the American Relief Administration came of its own accord to the assistance of those hospitals, supplying them regularly with medicines, instruments, things needed for the care and treatment of the patients, linen, blankets, gowns, and also took upon itself the supplementary feeding of the patients.

"This assistance has greatly improved the condition of the patients and has also helped to check disease in general.

"Being aware of the great good done by the humanitarian activities of the American Relief Administration, the chief physicians of the Moscow hospitals are conveying to that organization in the person of the chief of the Moscow section their sincere appreciation for its present activities and its readiness to continue that work in the future."

AWARD OF THE CHARLES G. MICKLE FELLOWSHIP.

This fellowship, under the control of the faculty of medicine of the University of Toronto, represents the income from a \$25,000 endowment by the late Dr. W. J. Mickle. The fellowship is awarded to physicians anywhere who have made distinct contributions to practical knowledge of medicine.

The award has been made to Dr. Harvey Cushing, professor of surgery at the Harvard Medical School and chief of the surgical service of the Peter Bent Brigham Hospital. Dr. Cushing has accepted the award but has requested the faculty of the University of Toronto to send one of its young graduates to work with him. He will transfer the money to this person.

Dr. Cushing, after graduation from the Harvard Medical School, was surgical house officer in the Massachusetts General Hospital. Later he went to Johns Hopkins, serving as professor of surgery for nine years, and after that time returned to Boston.

Dr. Cushing was elected president of the College of Surgeons at the last annual meeting and is an honorary fellow of the Royal College of Surgeons of England and Ireland. He served as director of Base Hospital 5, attached to the British army from May, 1917, to May, 1919.

The bestowal of this award is a recognition of

the position held by Dr. Cushing in the surgical world as well as of his service in the World War.

FRAMINGHAM MONOGRAPH No. 9.—This last of a medical series issued by the Framingham Community Health and Tuberculosis Demonstration deals with the Framingham epidemic and presents post-epidemic observations and will be reviewed later. This valuable contribution to the literature devoted to the problems of influenza may be procured by applying to the Community Health Station. The price is five cents a copy.

RECENT DEATHS

DR. GEORGE EDGAR LOTHROP, long identified with the theatrical profession, formerly a practising physician in Boston, died at the Massachusetts General Hospital, August 3, 1922, at the age of seventy-one. He was born in Providence, R. I., November 17, 1850, was left an orphan at the age of ten, supported himself by selling papers and finally worked his way through Dartmouth Medical School, taking his degree there in 1871. After some fifteen years of practice, Dr. Lothrop devoted himself to theatrical management, opening the Boylston Museum and later the Grand Museum. For thirty-five years he had been manager of the Howard Athenaeum. Among his memberships were the Elks, Masons and the Odd Fellows. In recent years he had lived in Brookline. He is survived by his widow and one son.

DR. PETER WHITE COOY, of Lawrence, a fellow of the Massachusetts Medical Society, died at his home, July 15, 1922, aged 64, from the effects of a fall.

He was a graduate of the College of Physicians and Surgeons, Keokuk, Iowa, in 1882, and joined the State Medical Society in 1916.

The profession will feel profound sympathy for Dr. Joel E. Goldthwait in the loss of his son, Vincent Bowditch Goldthwait, by accidental drowning, August 9, 1922.

REPRINTS.

A few reprints of *The Treatment of Diabetes Mellitus*, by Elliott P. Joslin (BOS. MED. AND SURG. JOUR., June 22, 1922), are available and may be procured by applying at this office. Price 50c.

BOSTON MED. AND SURG. JOURNAL.

ROENTGEN RAY AND TUBERCULOSIS IN INFANTS AND CHILDREN.

A SUMMARY OF SEVENTY-EIGHT CASES.

BY FREDERICK W. O'BRIEN, A.B., M.D., BOSTON.

Assistant Professor, Tufts College Medical School;
Consulting Roentgenologist, Boston Consumptives'
Hospital.

and

FORREST B. AMES, A.B., M.D., BOSTON.

Assistant Roentgenologist, Boston Consumptives'
Hospital.

It is an obvious fact that in all scientific investigations proceeding over a period of years the pendulum of inquiry swings gradually across the entire field and now one phase of the subject and then another becomes the centre for more detailed consideration.

No exception to this appears in the study of tuberculosis. Not so long ago the adult was the one on whom attention was bestowed. Of late, however, interest is changing, and present day ideas may be summed up in the words of Griffin, who says: "If, therefore, tuberculosis practically always starts in childhood, as we must admit it does by the evidence given us by competent observers, the way to eradicate it is not by sanatorium care of adults, but by preventive care in childhood."

Preventive care of any individual must of necessity rest on methods of procedure which will indicate that such care is necessary in a given case.

Methods of procedure for the diagnosis of tuberculosis in infancy and childhood are well established and widely used. These methods consist of a careful history, an equally thorough physical examination, roentgenograms and laboratory tests. He is the best diagnostician who will rely on no one finding, save positive sputum, but will correlate all methods to form a correct diagnosis.

Apparently, however, even with all these careful methods of precision in diagnosis, a more nearly correct estimate of the clinical types of tuberculosis in childhood has not been made until within the past year.

Early in 1921 the present writers offered a statistical study² of forty-four infants and children at the Boston Consumptives' Hospital. The purpose of this study was to correlate roentgen ray findings with clinical tests and clinical manifestations of tuberculosis as they appeared in infancy and childhood.

Summarizing these cases, we concluded:

- (a) The Von Pirquet and intracutaneous skin reactions are reliable guides to infection with tubercle bacilli, and the number of positive reactions increases from infancy up through childhood, over ten years of age, all patients reacting.
- (b) In twenty-six of thirty-six positive skin reactions the roentgen ray disclosed the site of infection to be intrathoracic.
- (c) D'Espine's sign, as a clinical index of tuberculosis of the bronchial lymph nodes, is of relatively little value, being elicited only eleven

CASE 1. Boy, now 14 years of age. Excellent clinical condition. Positive sputum. Steadily progressive lung pathology similar to adult type.

CASE 2. Boy, now 14 years of age. Clinically positive for the past four years. Positive sputum. Marked progression of lesions since past year, with extreme prostration of patient with typical adult symptoms.

Case 3. Boy, now 12 years old. Negative from standpoint of symptomatology and physical examination. Discharged from hospital. Serial plates show thickening of hilus shadow and some progression toward periphery.

Case 4. Boy, now 10 years of age. Clinically negative. Serial roentgenograms show clearing at right base and calcification in right hilus region.

Case 5. Boy, now 10 years of age. Serial study shows apparent partial clearing of pulmonary lesions and development of cardiac involvement.

times, as against roentgen ray evidence of glandular enlargement in twenty-eight cases.

"3. Three cases of positive sputum were found in fourteen diagnoses of chronic pulmonary tuberculosis.

"4. Fourteen cases of chronic pulmonary tuberculosis of the adult type were found. This suggests that the so-called 'phthisis' is more common in childhood than has been stated by writers of textbooks.

"5. Fifteen cases, negative clinically, showed definite roentgen ray signs of marked structural changes consistent with tuberculous infection. This raises the question as to whether these children are to be regarded as more likely to develop clinical tuberculosis, and should thus be watched carefully and roentgenographed at fairly frequent intervals."

Feeling that a new line of attack on the questions concerning tuberculosis in children has been opened by these studies, we have continued our investigations and now add thirty-four cases to those previously reported.

In the light of time and other investigations our corroborative finding relative to the value of Von Pirquet and intra-cutaneous tuberculin tests seems to be amply proved. Therefore, in our new series of cases we have omitted these data.

Also, a further clinical discussion of the D'Espine sign seems unnecessary, accepting the logical conclusion that the roentgen ray is the best diagnostic means to determine the nature and extent of tracheo-bronchial lymph node involvement.

Our chief points for present discussion deal with: (1) The prevalence, in our group of cases of chronic pulmonary tuberculosis in infants and children; (2) a comparative consideration of roentgen ray findings and clinical diagnosis; (3) presentation of a few cases emphasizing the value of serial roentgenography in preventive work among children.

CHRONIC PULMONARY TYPES IN CHILDREN.

With the new interest being given to a study of types and clinical progress of tuberculosis in childhood, we naturally come to the question concerning the prevalence of chronic pulmonary forms. Are these forms more common than we have been led to believe?

This is certainly a fair question, and an important one, for if the child can, and does, have chronic, slowly progressive types of tuberculosis, our needs for prophylactic and sanatorium care of suspected and frank cases are imperative. If we can apply methods of treatment early enough, then, it is logical to assume we can carry more children through a clinically healthy adolescence and, by the effects of early training, insure to them a reasonably long and useful adult life.

One writer, Griffin¹, would estimate 20,000 definitely tuberculous children in the country with a pitifully small number of sanatoria to care for them. Fishberg² says he has seen scarcely twelve cases of chronic pulmonary tuberculosis in several thousand children.

Apparently between these wide extremes there is a conservative middle estimate. Appar-

ently, too, this conservative estimate is much larger than medical men have generally conceived.

Textbooks on diseases occurring in infancy and childhood lay but little emphasis on the incidence of chronic pulmonary tuberculosis. Bone and gland tuberculosis are said to take first place⁴, and the general impression is given that the chronically progressive lung lesions are sufficiently rare to need but little stressing.

Only within a short while have observers begun to assert more often the widespread prevalence of pulmonary types in childhood.

In our previous study we noted fourteen cases of chronic pulmonary tuberculosis in forty-four children under fourteen years of age, seven of these being in the age groups under ten years and two under six years of age.

Bringing this series to date by adding thirty-four cases, we have found six more with chronic pulmonary tuberculosis, three under ten years of age. In addition to these six on whom definite diagnosis was made, three more patients were placed in the questionable class from clinical manifestations.

Three of the above cases were found to have positive sputum. Other diagnoses were made on the basis of positive findings by methods of procedure already mentioned, *i. e.*, clinical history, physical examination and roentgen ray. The roentgen ray was corroborative in all cases and showed characteristic and well defined changes in the lung fields, ranging from hilus and peribronchial thickening to infiltration and consolidation.

In the face of these additional figures we again feel justified in the assumption that chronic pulmonary tuberculosis occurs in children more often than has been stated and sufficiently often to deserve more attention than has heretofore been given to it.

ROENTGEN RAY AND CLINICAL FINDINGS.

In an attempt to emphasize the increasingly practical use of the roentgen ray as a diagnostic aid, we noted in our previous study fifteen cases in which the physical findings were negative, while the roentgenogram showed structural changes within the lung fields consistent with pathology caused by the tubercle bacillus.

With this point we enter a field of controversy, for with the attention of clinicians and roentgenologists newly focused on a correlation of the types of lesions and clinical findings in children, there is some discussion as to what is a real norm with which can be compared roentgenograms of suspected cases.

It is probably true that an absolute norm can be found only with difficulty, if at all, yet with the work at its present status, we feel justified in assuming certain changes in the lung markings as consistent with tuberculosis if like appearing changes, and no others, occur in cases of well proven tuberculous disease in children.

Only by adhering to certain standards of diagnosis can we assume to ourselves an accuracy of reasoning which can be regarded as such until definitely proved fallacious.

Least this attitude be misunderstood, we reiterate the absolute necessity of correlating clinical and roentgen ray findings, and would, by no means, advocate the making of a positive diagnosis on the basis of the roentgen ray alone, giving the benefit of the doubt to the patient in each case where symptomatology and physical examination are entirely negative.

However, we do feel that differences of opinion can be settled only by constant observations of children who show definite structural lung changes by roentgen ray with and without clinical signs and symptoms.

In our new series we have found eight cases with changes in the lung fields consistent with tuberculosis from the standpoint of roentgen ray, but negative clinically. We believe it is fair to assume that these children do have demonstrable sites of infection with tubercle bacilli, and because of this should be traced along through childhood and roentgenographed at intervals to note progression or retrogression of so-called positive lung markings. This is one method of preventive work under our present day conception of prophylaxis.

SERIAL ROENTGENOGRAPHY.

Following the lines of study just suggested we have endeavored to add new data to cases previously reported.

As already stated in our former series, we found fifteen cases with characteristic lung field markings on the roentgenogram, but clinically negative for tuberculosis.

During the year's interval ten of these children have been discharged from the hospital clinically well. We have endeavored to follow up these ten through the Out-Patient Department. Only five have been found and returned for re-examination. With the five still remaining in the hospital we thus have ten cases in this class of children on whom serial roentgenograms have been made.

Of the ten cases we found that five showed definite changes in the roentgenograms, all of these changes being consistent with progression of the pulmonary lesion. Two of the five showed cardiac shadows pointing toward the presence of heart involvement.

Although the number of cases here reported is small, we feel that the value of their serial study is real and that the prophylactic principle involved should receive more widespread adoption.

The accompanying cuts of serial roentgenograms are of two types of cases: (1) Two clinically positive cases in which very definite progressive pulmonary involvement has taken place over a period of one to three years; and (2) three cases which are regarded as clinically

negative, yet have shown changes in lung markings by roentgen ray. The developed cardiac lesion is well shown in one case.

SUMMARY AND CONCLUSIONS.

We have presented a supplementary group of thirty-four infants and children, studied from the standpoint of correlating roentgen ray and clinical findings. These thirty-four cases are added to forty-four previously reported. From this new group and total of seventy-eight cases we have found the following:

1. A complete total of twenty cases of definite chronic pulmonary tuberculosis in seventy-eight children under fourteen years of age, or twenty-four plus per cent. Ten, or fifty per cent. of these cases were in children under ten years of age.

In spite of the apparent concentration of tuberculous cases at the Boston Consumptives' Hospital we believe this large number of positive findings points to more widespread incidence of pulmonary tuberculosis in children than has yet been sufficiently emphasized.

The roentgen ray was of definite help in determining site, extent and type of lesion in each of the positive cases.

2. Eight patients were examined in whose lung fields the roentgenogram showed typical markings consistent with pathology caused by tubercle bacilli. These cases were negative clinically. Inasmuch as the prophylaxis of tuberculosis is more and more being begun in childhood, the roentgen ray evidence of pulmonary involvement may safely be taken as a warning, and certain positive cases should receive more detailed attention and treated along preventive lines.

3. Ten cases from our old series were re-examined by roentgen ray. These cases were clinically negative, but had shown positive lung field markings in previous roentgenograms.

Five from these ten showed changes consistent with progression of the pulmonary condition; two showed development of cardiac lesions.

From these we conclude that serial roentgenograms should become a routine part of methods of procedure in the diagnosis and preventive treatment of tuberculosis in infants and children.

INTERSTITIAL PREGNANCY, WITH REPORT OF A CASE OPERATED BEFORE RUPTURE.

By G. A. MOORE, M.D., F.A.C.S., BROCKTON, MASS.

Gestation within the cornual portion of the tube was first recognized as a pathological entity about two centuries ago. All reported cases up to 1893 were observed upon the autopsy table. If the diagnoses were made or suspected before or after rupture in the early days of surgery, no mention of this fact has been found in the literature by the writer. After rupture, the sudden alarming symptoms of shock and hemorrhage which intervened were treated expectantly with the result of 100 per cent. mortality.

The year 1893 marks a new era in the treatment of this condition, when Traub¹ operated on a case after rupture. A supravaginal hysterectomy was done with recovery.

Few surgical lesions of the genital tract in women are of rarer occurrence. The first case observed by an American author was reported by Fitz² in 1875, who found 18 cases in the literature up to that time. Ten years later Simon³ stated that he could find but nine cases of true interstitial pregnancy in the literature, and nine doubtful.

In 1896 Rosenthal⁴ studied 1324 ectopic pregnancies of all types and found 40 of them to be undoubted interstitials, an occurrence of 3 per cent. Werth⁵ and Weinbrenner⁶, who studied this subject at about the same time, questioned the high percentage of cases found by Rosenthal.

The most exhaustive study of interstitial pregnancy to date was made by Waegeli⁷ in 1914. After a careful study of records and available specimens, he could accept but 53 of the 150 cases he found reported. He reported two cases, making a total of 55 cases up to that time. Up to the time his article was written (1914), there were but 11 reported cases operated upon before rupture occurred.

Of 304 ectopic pregnancies treated at Johns Hopkins Hospital, and reported by Wynne⁸ in 1918, there were but two accepted by the pathologists as true cornual, seven tenths per cent. He reported a total of 1547 ectopic pregnancies of all types, of which number there were 18 interstitials, an occurrence of 1.16 per cent. From 1914 to the present time reports of 26 cases have been found in the literature by the writer, making a total, with the cases accepted by Waegeli, of 79 cases. About 20 of these came to operation before rupture.

To be classified as true interstitial pregnancy, the gestation sac must lie within the wall of the uterine cornu between the proximal end of the isthmic portion of the tube and its uterine orifice. The old definition, that the sac shall lie within the lumen of the tube, is too dogmatic. The tubal mucosa in the vicinity of the sac has been observed in but very rare instances in these cases.

In the normal uterus the interstitial portion of the tube is about 1 cm. long by 1 to 1.5 mm. in diameter. It forms an arc, convex upward and forward. The folds of mucosa within this portion of the tube are fewer in number and not as deep as those found in the isthmus portion. In occasional cases crypts and rudimentary canals have been found opening into the lumen. The epithelial lining does not differ from that found in the isthmus portion of the tube. It is cylindrical with vibrating cilia.

Many theories have been advanced as a cause of this interesting condition. They can well be classed under two heads: (1) Anatomical, and (2) Pathological. Of the anatomical causes, a rudimentary canal of Gärtner as suggested by Pfaff,⁹ or of Wolff, mentioned by Leopold,¹⁰ deserve consideration. Frankl's¹¹ statement, that diverticulae as a cause are of utmost importance, may, with further study, receive more general acceptance. Congenital atresia may be a causative factor, especially in cases where the passage of the ovum to the interstitial portion of the tube has been delayed by adhesions, inflammations, etc., permitting abnormal development.

Breschet¹² advanced the theory that the uterine ostium of the tube became closed by inflammation during the passage of the ovum through the tube. The ovum then penetrates into the wall of the uterus through a vein of the tube.

Hennig¹³ described a sphincter muscle about the uterine orifice of the tube. In cases where the ovum was delayed in its passage through the tube, contractions of the sphincter closed the orifice of the tube, leaving the ovum in the interstitial portion. Inflammatory processes, although rare in this situation, may well result in atresias, angulations, etc., which impede the passage of the ovum. Development of the ovum would finally result in its arrest in the interstitial portion of the tube.

Microscopic study of specimens of interstitial pregnancy, with a view to ascertaining the cause, has excited little interest in the past among students of this subject. We must admit, as did Velpeau in 1831, that the cause is still unknown.

Morbid anatomy and clinical symptoms of the disease are dependent to a great extent upon the site of lodgment and direction of growth of the ovum. Hypertrophy and hyperplasia of the parenchyma of the uterus about the gestation sac, coincident with the development of the sac, are the factors which determine the gross appearance of the fundus as well as the abnormal relationship of the appendages.

If the ovum lodges near the uterine ostium of the tube, development of the sac does not result in marked asymmetry of the fundus during the early weeks. In cases where the sac is situated near the periphery of the uterus, marked asymmetry of the fundus is an early symptom. Growth of the sac undoubtedly occurs in the direction of least resistance; the thickness of the uterine wall over the sac deter-

mines the direction in which growth will take place.

In the former group of cases with implantation near the uterine cavity, development is toward the cavity. It is believed by many writers that a certain percentage of these cases rupture into the uterine cavity, and are followed by a typical abortion. A few cases have been reported where, on doing a curettage for abortion, the curette has entered a cavity in a cornu of the uterus. It is thought by some that in a few cases following rupture the placenta becomes reimplanted in the uterine cavity, and pregnancy continues to term. In recent years a few cases have been reported of the development of the sac on the anterior or posterior side of the uterus near the center of the fundus. Of especial interest are a case of this type reported by Pfaff after rupture, and one by Curtis¹⁴ before rupture. These cases would seem to confirm the theory of the ovum lodging in some diverticulum of the tube and coming to rest deep in the wall of the fundus.

In the latter group of cases, where the ovum lodges near the periphery of the uterus, development of the sac is outward and upward. Asymmetry of the fundus is an early recognizable sign, usually about the fourth to sixth week of development when the sac has attained about the size of a tangerine orange. In many cases the sign of Ruge-Simon is present: the fundus is vertical from the normal cornu upward to the gravid one, and the round ligament and tube on the gravid side are attached laterally. Rupture is practically without exception through the serosa into the general peritoneal cavity with the attendant symptoms of shock and hemorrhage of the most alarming degree. On account of the increased blood supply in the wall of the uterus, rupture of an interstitial pregnancy produces profound symptoms of shock and hemorrhage in many instances much more rapidly than rupture of a pregnancy in the isthmus portion of the tube.

The classification of interstitial pregnancy has been thoroughly discussed by Weinbrenner, Kohlmann, Lequeux and Waegeli. It is a subject of more academic importance than of especial clinical value. The latter author's proposed classification is the result of a study of a great many records and museum specimens, and is based upon the site of implantation and direction of growth of the ovum:

1. Interstitial intramural or paratubal.
 - (a) Evolution against the uterine serosa.
 - (b) Evolution against the uterine cavity.
 - (c) Evolution in both directions.
2. Canalicular interstitial pregnancy.
 - (a) With outward growth and rupture into the abdomen.
 - (b) With growth toward the uterine cavity and rupture into it.
 - (c) With symmetrical growth in both directions and a possible rupture into either cavity.

Interstitial pregnancy occurs more frequently in multipara than in primipara. In 39 cases studied by Waegeli, 32 were reported to be multipara. Owing to the fact that the uterine wall is capable of greater distention than the isthmie portion of the tube, rupture occurs in a majority of cases later than in tubal pregnancy, usually about the third to sixth month. External signs, as pigmentation, enlargement of the breast, etc., are therefore frequently found. Amenorrhea is of frequent occurrence, but in a majority of cases lasts only 3 to 4 weeks, and is followed by irregular flow simulating an abortion. Lower abdominal pain on the gravid side is common. Malaise, nausea, and vertigo are frequently symptoms of impending rupture.

Siefert¹⁵ stated that no interstitial pregnancy was seen after the sixth month. This has since been disproved by a case reported by Kupferberg¹⁶ at eight months, and one by Glaesner¹⁷ at seven months. Waegeli asserts that some patients have been known to go to term. Here again it may be stated that the amount of development before rupture occurs depends upon the site of implantation, the direction of growth of the sac and the amount of hypertrophy and elasticity of the uterine wall.

FIG. 1.—Left cornu and tube. The tumor was very tense and wall extremely thin on anterior surface.

On examination an elongated, softened cervix is first noted, then a tumor on the gravid side. In my case, to be reported, my first thought was a fibroid. The tumor extends up vertically, giving one the impression that the fundus is turned one quarter way around toward the normal side, and a straight line is formed upward from the normal tube to the peak of the tumor. In such cases the round ligament is attached laterally to the tumor, sign of Ruge-Simon, the condition found at operation in my case. Judging from reported cases, this observation is rarely made before operation. Virchow stated that the round ligament was always outside the gestation sac. As his observations were made at the autopsy table, we may infer that they were cases of longer term than many early cases of recent report. In these early cases, where a small tumor is encountered, the relations of the round ligament, adnexa and fundus are little changed.

The tumor may be painless, but is frequently tender to touch; no pedicle or line of demarcation

between it and the fundus can be felt. It is usually firm and tense, but in late cases fluctuation may be felt.

After rupture has occurred, it is rarely possible to palpate a tumor on account of the signs of acute peritoneal irritation. In a few cases a haematoma has formed following the initial symptoms of rupture, which have suggested the diagnosis. In most, the immediate symptoms of intraperitoneal hemorrhage dominate the picture and diagnosis of ruptured tubal pregnancy is made.

While a diagnosis of ectopic pregnancy is frequently made, with the inconclusive symptoms presented, it is hardly to be wondered at that a positive diagnosis before operation is extremely rare, if it has ever been made, and that operation before rupture is of very uncommon occurrence.

Few recent writers have made an extensive study of the pathology of interstitial pregnancy. Of those who have been interested in this phase of the subject, Waegeli's description may be accepted as the most authoritative.

FIG. 2.—Tumor bisected, with foetus and placenta in upper half.

Where a communication is found between the sac and the uterine cavity, it is invariably due to a tear in the muscular septum between the two and not the result of dilatation of the uterine orifice of the tube. In a study of 25 cases, the muscular septum between the sac and uterine cavity varied from 3 mm. to 2 cm. in thickness. There were but 10 cases up to 1914 in which a communication was found between the sac and uterine cavity, according to Waegeli. I have found none reported since.

The interstitial portion of the tube external to the fetal sac is frequently seen, but the part between the sac and uterine cavity is rarely observed. Strobaek¹⁸ reported a case in which both the proximal and distal portions of the tube were visible, and Waegeli was able to trace the tube in one of his cases throughout its entire course. It passed around one side of the sac but did not enter it. The latter case illustrates the view expressed by Frankl, that the ovum lodges in a diverticulum outside the lumen of the tube. Kuhne,¹⁹ Aschoff,²⁰ and

others believe that in most cases the fecundated ovum lodges outside the lumen of the tube.

Mortality statistics of interstitial pregnancy are to a great extent dependent upon the time elapsing between rupture and operation. Patients operated upon before rupture may be disregarded, as no deaths have been reported as yet in these cases. Expectant treatment, which was universally practiced up to 1893, resulted in 100 per cent. mortality. In most cases death resulted within the first twenty-four hours from hemorrhage and shock; rarely the patient survived the initial symptoms, and died of infection several days later.

In a series of 29 cases of operation following rupture, reported by Waegeli in 1914, there were 21 recoveries, a mortality of 27 per cent. Wynne in 1918 reported 82 operated cases with a mortality of 11.9 per cent. He does not state whether rupture had occurred in all before operation. The reports in recent years show a decreasing mortality, which is apparently due to earlier recognition of symptoms of rupture, with earlier institution of surgical measures and more efficient methods of treating hemorrhage and shock.

The treatment of interstitial pregnancy is immediately surgical, when the diagnosis is made or suspected. In most cases the presenting symptoms are those of rupture of a viscus with sudden, profuse intraperitoneal hemorrhage. A positive diagnosis has rarely been made before operation. Since surgical treatment was instituted for these cases, there have been no adherents of expectant methods as is the case in ruptured tubal pregnancy.

Transfusion during operation or immediately after in critical cases, next to arrest of the hemorrhage, is the greatest aid.

The type of operation must depend upon the individual case. The vaginal route, either by dilatation and curettage of the sac, or hysterectomy should be rejected in all cases. Curettage is a dangerous and unsurgical procedure and has been reported in but two instances. Frankl attempted this method through a diagnostic error, and followed it with a vaginal hysterectomy. Farrar²¹ opened the abdomen and found an unruptured interstitial pregnancy and then curetted from below with a hand on the sac to prevent rupture. Vaginal hysterectomy is time-consuming and in many cases a needless sacrifice. Neither method has found favor in the treatment of any type of interstitial pregnancy.

Engstrom²² in 1896, and Lawson Tait²³ in 1893, each reported a case treated before rupture by incision of the sac, evacuating the contents and closure. Two other cases treated by this method were reported by Wynne.

The method of choice is excision of the sac and tube on the gravid side and closure of the uterine wound. In all unruptured cases, except those operated late in pregnancy, this treatment may be adopted. Also in ruptured cases when

there is not great loss of blood or destruction of uterine tissue, excision is to be preferred.

If the patient's condition is grave as a result of shock and hemorrhage, or the uterus is crippled by the rupture, supravaginal hysterectomy is the method of choice. Bleeding can be controlled more quickly than by excision and it is attended with little shock.

Infected cases, where the patient's condition permits, should be treated by pan-hysterectomy.

In a series of 66 cases studied by Wynne, hysterectomy, either total or subtotal, was practiced in 21 cases, and in the remaining 45 excision of the sac, with or without removal of the tube and ovary on the gravid side, was done.

Of 33 cases reported by Waegeli, total hysterectomy was done in 10, supravaginal in six, and excision of the gravid horn and adnexa in 17.

CASE.—MRS. O'H., age 27. Referred by Dr. John A. Pettey of Brockton, February 11, 1920. F. II. Married five years. Husband living and well. One child living and well, no other pregnancy. P. II. Usual children's diseases. Pneumonia twice during childhood. Peritonissilar abscess eight years ago, no other illnesses. Catamenia regular and normal until recently. Bowels normal. Never jaundiced. No urinary symptoms. P. I. For the past several months catamenia has been very profuse every other month. No dysmenorrhea. September, 1919, catamenia was excessive in amount but not prolonged. The October period was normal. In November a profuse flow began about the 28th and continued a few days in December. Flowed again about Jan. 2, 1920, very profusely and continued five days, then ceased for five days. Since that time, Jan. 12, she has flowed almost constantly, but has had no profuse flow. Walking or turning quickly in bed has caused a sharp pain in the left side of the abdomen low down. No discomfort on sitting. Considerable frequency of urination since Jan. 1; no dysuria. Bowels normal. No nausea or vomiting. She was examined by Dr. Pettey about Jan. 1, who found the uterus freely movable. Vaginal examination yesterday, Feb. 10, 1920, by Dr. Pettey, who found a mass on the left side of the uterus. He was positive this had formed since the date of last examination, Jan. 1. A tentative diagnosis of ectopic pregnancy was made by him on referring the case to me. P. E.—Well developed and nourished. Skin good color. Pupils equal and react normally. Teeth—upper false, lower in good condition. Throat normal. Heart and lungs normal. Blood pressure 130. Pulse 80. Temperature normal. Abdomen level, tympanitic throughout, no masses or tenderness except in the left lower quadrant, just above the symphysis, where a very tender mass about the size of half an egg can be felt. Vaginal examination: slight laceration of perineum and bilateral laceration of cervix. Cervix is soft and patulous. Uterus moderately enlarged, fundus tipped toward the right and extending upward

from the left side of the fundus is a firm, tender mass, about the size of a tangerine orange. This mass is definitely connected with the fundus, no line of demarcation between it and the fundus made out. Tubes and ovaries apparently normal. Diagnosis: The firm consistency of the mass, with the fact that it was definitely connected with fundus misled me into making a first diagnosis of fibroid. Irregular menstruation and pain, together with the fact that no mass was palpable on examination six weeks ago pointed toward pregnancy. As the mass seemed to be definitely a part of the uterus, a second diagnosis of interstitial pregnancy was made.

Feb. 16, 1920. Operation at the Moore Hospital. Ether. Dr. Pettcy, Asst., Dr. J. J. Condrick, Trendelenberg position. A five-inch median suprapubic incision. Fundus moderately enlarged, tipped far over to the right. In the left cornu of the uterus is a dark purplish, cystic mass about the size of a tangerine orange, extending upward, slightly to the left. The peak of the tumor extends up somewhat above the attachment of the left tube. Both tubes and ovaries normal. The encroachment of the tumor upon the fundus seemed to involve only the left cornu. A conservative operation was therefore decided upon. The tumor was removed by a wedge-shaped incision in the body of the uterus, the left tube being included. The uterine cavity was not opened during the operation. Incision in the uterus was closed with double No. 2 iodized gut and broad ligament sutured with continuous suture. Abdomen closed in the usual way. Convalescence was uneventful and the patient was discharged March 2, 1920.

On account of the rarity of an unruptured interstitial pregnancy, the specimen was taken to a pathologist for detailed study. It was mislaid and several months later found in such a poor state of preservation that it was of no value. A photograph was taken of the tumor on the day of operation, however, which shows a true interstitial pregnancy.

UNRECOGNIZED FRACTURE OF SPINE.

MILTON G. STURGES, M.D., SEATTLE, WASHINGTON.

IN palpable fractures of the spine it has always been recognized that there existed a certain percentage of cases in which cord symptoms were absent or only temporary. There is in addition even a greater percentage of cases in which there is no diagnosis of fracture made at the time of injury or shortly subsequent. This class of case has been attracting an increasing amount of attention in recent years; increasing in direct proportion to the increase of power in x-ray machines and the more frequent use of those adventitious aids eliminating factors of error. It has been termed "Kuemmel's disease," since in 1895 Kuemmel reported five such cases, endeavoring to correlate and picture the symptoms in such a way as to facilitate diagnosis. This seems a futile effort, since the character of the lesion, its location, which must consider mobility, and the amount of muscle pull, the amount of weight-carrying function; the presence or absence of nerve-root pressure; in fact those factors which enter into the final picture must, *per se*, have so great a variation that no formula can encompass them.

The diagnosis rests on the history of indirect or direct trauma to the spine, associated with any symptom or symptoms of sufficient importance or duration to warrant an x-ray investigation, which should include a lateral as well as a stereo, and which should be of sufficient clearness to enable one to see the bodies of the vertebrae distinctly, for much of the error that has crept into these cases has been the result of guessing.

A peculiar feature of the symptomatology, as pointed out by Sever, is that symptoms may not appear for a period of several months or even years. This naturally is dependent on the extent of injury and the location and function of the vertebrae affected, as well as the vocation of the patient. It has seemed to the writer that fractures in the lower thoracic region are more likely to produce early symptoms and a greater disability, since the thoracic vertebrae, in addition to their weight-bearing function, being the point of rest from which the muscular action of the whole shoulder girdle arises, are subject to a leverage in direct proportion to the amount of that muscular effort, and as a consequence symptoms arise much more quickly than even in the lumbar region, where the muscular pull is less and the increased size of the vertebrae offset the added weight-carrying function.

The pathology in those cases of considerable duration is distinctive—a disappearance of the body of the vertebra along with the contiguous inter-vertebral discs and possibly the articular surfaces of the two adjacent vertebrae. Naturally this process is more marked on the front of the vertebrae because of the greater resistance of the denser bone constituting the neural-arch,

which, with its ligaments and tendinous attachments, has less pathologic motion than the body. This process has been termed "spondylarthrititis" by Kummel, "spondylo-malacia" by Schede; but it is probably caused by the absorption of bone due to the increased mobility of that particular segment by reason of the fracture, with the associated attrition arising from the inclusion of the products of osteoblastic activity within the joint surface itself.

It is bromidic to state that the treatment varies according to the location, character and severity of the original injury. Many cases have had no treatment whatever and are recognized only accidentally after the lapse of years. With other cases simple retention and rest in bed is sufficient. Others require the extended use of jackets and plaster casts over a considerable period of time. In other cases open operation—preferably autogenous bone transplant—is indicated. In selecting treatment one must consider, first, the amount of time which the patient may have to devote to his treatment, into which question enter the consideration of his vocation, his financial status, his number of dependents and the probable length of time of his future activity; second, the certainty or uncertainty of cure by conservative measures.

The autogenous bone splint is particularly indicated in those cases of lower thoracic or lumbar injury where the financial status of the patient precludes his devoting the long period of time necessary under conservative treatment, since his recovery is rapid, is certain, the result is permanent and there is no greater loss of mobility than by conservative methods. Also such procedure is indicated in all cases in which conservative methods do not yield relief from pain and discomfort, or where there is any progress of the lesion under rest in bed.

Case 1.—Male, 52 years old. Complains that he could not rotate his head. This has been so since his earliest recollection, but of late motion has been attended by some pain. Examination shows that he is able to rotate his head to the left only five degrees, while the rotation to the right is approximately fifteen degrees. Motion of the head on the axis is unrestricted. He denied injury but recollected that he had been told by his parents that when three years old he had fallen down a steep bank, striking his forehead on a rock at the bottom, from which he was confined to bed for some time. He has no recollection of the injury. The x-ray (Figure 1) is difficult of interpretation. It can be safely asserted that the seventh vertebra was not fractured, that the involvement of the sixth probably came as a later result of the original injury. What happened to the others is problematical. There probably was a fracture of the fourth, fifth, second, and possibly the third, but without dislocation. The body of the fifth seems to have disappeared. Nature has compensated this abnormal mobility by an extraordinary down-

FIG. 1.

FIG. 2.

ward growth of the spines of the second, third, fourth and fifth, which, overlapping, give a measure of stability. There was no involvement of any of the nerve segments and the patient was totally unconscious of his having so serious a lesion, since never having known any other condition the lack of mobility was to him normal.

Case 2.—Railroad fireman, 32 years old, 5 feet 11 inches tall, weighs 180 pounds, good physical condition and well muscled. In December, 1915, through some negligence the air was not coupled up as his train entered the east portal of the tunnel through the Cascade Mountains, which is about two miles long with a 2 per cent. grade sloping toward the west. The engine alone was unable to hold the train, which emerged from the tunnel at an estimated speed of seventy miles an hour. The fireman, at his first opportunity, jumped, rolled down the embankment, plunging into a deep pool of water, and received only a Pott's fracture of the right leg. He consulted me some three months later. Examination disclosed the fact that his right hand grip was not equal to his left; that the spine of the first dorsal vertebra was apparently out of line about one-half inch. His right arm was otherwise practically negative and his disability so slight that it had not interfered in any way with his normal range of activity. X-ray disclosed the fact that he had a vertical fracture through the middle of the body of the fourth cervical vertebra, passing down to the right side of the fifth and out through the transverse process of the sixth cervical vertebra.

These two cases illustrate the fact that the injury may be very serious with little or no disability. The first patient, having never known any condition other than that of restricted mobility, was not conscious that this was abnormal. The second patient, as the result of a severe trauma, had received a very dangerous cervical fracture which he might have noticed had it not been associated with a fracture of his right leg, but there was not sufficient disability to draw it to his attention until it was discovered by the x-ray.

Case 3.—Male, 22 years old, average muscular development. Was unloading cordwood from a cart; his horses became frightened and he was thrown to the ground, striking his back against a block of wood. Although suffering considerably, he was able to walk a mile to his home. I saw him two years later, in 1916. He stated that during this time he had suffered much, particularly in getting into and out of bed—a process usually occupying about ten minutes. He first had to roll over on his stomach, raise himself on his hands and knees, progress sideways to the edge of the bed, get one foot on the floor, then the other, and push himself into an erect position, which process was reversed on retiring. He complained that his back was stiff, that he had constant pain at about the site of

the injury, that he could not move quickly. Examination disclosed slight kyphosis over the third lumbar vertebra, accompanied by spasm of the spinous muscles. All motion was restricted and associated with pain. X-ray disclosed a fracture of the third lumbar vertebra, the body being reduced to about one-third of its usual size, with a disappearance of the intervertebral discs and the articular surface of the two contiguous vertebrae. An autogenous bone split operation after the manner of Albee was done; patient was in bed six weeks and was discharged cured. He has worked hard since without discomfort.

Case 4.—Male, 28 years old, lineman. Was removing the wires from a telephone pole, which broke at the base and fell while he was still on it. He apparently landed on his feet, and the pole, striking him on the right shoulder, fell across his right shoulder girdle, but, being held by two wires still attached, it squeezed him without fracturing any of the bones. I saw him within an hour. He had an abrasion over his right scapula about three by four inches; he complained of some pain about the lower part of his back, but palpation showed no abnormality; knee jerks were accentuated. An x-ray was ordered to discover a fracture, if present, but was reported as negative. At his request his family physician cared for him and I did not see him again until October 29, when he came in for examination and permission to return to work. At this time there was a marked kyphosis at the level of his eleventh dorsal vertebra. He stated that he tired easily and on tiring pain appeared at this point. He had a slight Babin-ski in his right foot, decreased right patella reflex, exaggerated left patella reflex. There was no appreciable or constant loss of sensation to heat or cold. X-ray shows fracture of the eleventh dorsal vertebra, beginning about the middle of the base, extending upward and emerging at the base of the transverse process, with slight outward displacement of this fragment. There is considerable callus formation surrounding this. Lateral view shows characteristic lesion—a wearing away of the inferior surface, more marked anteriorly. He refused treatment and left the city shortly after.

Case 5.—Examination March 14, 1922. Male, 32 years old, painter. In April, 1921, fell about eighteen feet, striking on his back. He was moderately shaken up by the fall, but was able to return to work, and had worked steadily since, but states that when he leans over for a considerable period of time he has a sharp pain in the middle of his back. This was first noticed in September and has increased steadily. Examination discloses very little limitation of motion, but on full forward bending there is some tenderness along the middle of the thoracic vertebrae. X-ray shows fracture of the eighth thoracic vertebra with attrition of lower articular surface only.

Case 6.—Examination March 13, 1922. Male, 72 years old, tailor. While journeying to Seattle on one of the "mosquito fleet" he stepped out on deck and stood beneath the freight elevator, which, descending suddenly, struck him on the shoulders. On arrival he was sent to the Seattle General Hospital. Examination showed abrasion and redness over both shoulder blades; there was no evidence of trauma elsewhere about the body; his reflexes were normal excepting that he had a suggestion of Babinski in both feet and both knee jerks were exaggerated; there were no areas of sensory interference. On movement he complained of pain at about the middle of his lumbar spine, and an x-ray disclosed a horizontal fracture extending through the body of the third lumbar vertebra. This case, however, because of his age and the added fact that the fracture does not involve either articular surface, is being treated by apparatus and is progressing favorably.

Case 7.—Male, 21 years old. In April, 1921, while in Yokohama, Japan, employed as seaman on one of the Shipping Board steamers, he fell through an open hatch, falling forty feet, striking squarely on his chest. He was removed to a hospital, where he recovered consciousness some hours later. He lost two front teeth and received a fracture of the second metacarpal bone of the right hand. He states that he was unable to turn over, but so far as he can recollect there was no interference with either motion or sensation in his legs. Six days later he was removed to his ship and brought to the Marine Hospital in Puget Sound, where he remained six weeks. He states that after his discharge he was unable to perform any heavy work, that he also tired very easily. He further states that this feeling of weakness has been increasing and that while lying in bed his left leg becomes numb. Examination: There is a moderate deformity of the second metacarpal, right hand, with about three-eighths of an inch shortening; there is some dislocation forward and outward of the inner end of the left clavicle. There is also a diagonal deformity of the sternum from about the third to the fifth rib, running down from left to right. He has a marked backward bowing of the thoracic spine, and on being asked if he has grown shorter in stature, states that he is "shrinking;" measurement shows that he is one and three-quarter inches shorter than at the time of his physical examination in the general draft. There is a palpable deformity at the level of the ninth thoracic vertebra, with seeming backward displacement of this vertebra on the tenth. The x-ray is unusual. It shows a healed fracture of the first left rib, of the left clavicle, of the sternum and the eleventh right rib. It also shows fracture of the fifth, sixth, seventh and ninth thoracic vertebrae, with considerable loss of substance of the bodies, and a fracture of the eighth thoracic vertebra, with some loss of substance on its lower surface.

Case 8.—Male, 32 years old, laborer, of good physique and well muscled. Was clearing "rigging" out of a tree when he slipped and fell twenty feet, striking on his head. He was unconscious for twelve hours or more. On recovering consciousness he suffered from severe headaches for three or four days, which persisted in diminishing degree until disappearance three weeks after the injury. I saw him first on the 25th of March, five weeks after his accident. He complained of stiffness of the upper spine and neck and stated also that in the morning his legs are numb and he has difficulty in moving them, but as the day progresses motion becomes freer. There is no pain on walking. Examination: Pupils are equal and react equally; blood pressure, systolic 122, diastolic 84; pulse rate 70. He holds his head rigidly; there is slight lateral motion, but scarcely any antero-posteriorly. His thoracic spine is held almost as rigidly as his neck, but there is very slight motion. Sensation is interfered with chiefly on the left side from the ninth rib down, there being patchy areas of partial or total anaesthesia on the left abdomen and both legs. Reflexes on the left side are absent in the morning, but are present in slight degree in the late afternoon. The right knee jerk is increased and the right plantar reflex slightly diminished. X-ray examination shows the cervical spine to be normal, but there is some compression of the fifth and sixth thoracic vertebrae, suggestive but not fully diagnostic of fracture. A lateral picture discloses a diagonal fracture of the body of the fifth thoracic vertebra, beginning on the posterior surface at the bottom of the neural-arch, extending along the base of the insertion of the neural-arch into the articular surface above.

Cases 3, 4, 5 and 7 illustrate the point, brought out by Sever, that the lesion untreated is progressive, and that although some time may elapse between the time of injury and the first discomforts arising, yet these tend to increase both in intensity and duration. Case 8 is too recent to warrant any deductions, but it seems undoubted that the same would hold true.

Case 6, a horizontal fracture through the body without involvement of either articular surface and without pressure on the spinal cord, should heal kindly under simple retention apparatus, but the normal process may be delayed because of his age and diminished vitality. From the character of the fracture it is probable that it would take place naturally even without immobilization.

In the treatment of Cases 3, 4, 7 and 8 operative procedure is indicated, partly on the lines laid down in the discussion of treatment. Since these men are all laboring men with dependents, the duration of disability being an essential consideration, but particularly in the eighth case, because of the extent of the lesion as well as the

positive pressure symptoms, which are likely to increase; and in Case 7 because of the progressive deformity arising from the extensive injury.

Medical Progress.

PROGRESS IN TUBERCULOSIS.

By JOHN B. HAWES, 2ND. M.D., BOSTON.

ANYONE at all acquainted with the vast amount of literature which is being written and published every day on the subject of tuberculosis and its various ramifications,—clinical, sociological, administrative, scientific, etc.,—will realize that it is almost an impossible task to condense into a comparatively few words a report of progress which will do real justice to the subject. It is possible in this report, therefore, to comment but briefly on what I consider to be the more important contributions and to refer readers who care to go into more details to proper sources of information. In this particular case the proper source of information, in my opinion, is that admirable journal—*The American Review of Tuberculosis*. The articles published in this monthly journal are of the highest quality while in addition, and of perhaps greater value, are the carefully written reviews of current literature on the entire subject of tuberculosis. Anyone, therefore, desiring information on this general subject should take the volume of the *American Review of Tuberculosis* for the past year, in which he will be sure to find the material which he seeks.

DIAGNOSIS.

I do not know of any particularly striking advance which has been made on the subject of diagnosis of tuberculosis during the past year. The various x-ray enthusiasts seem to be getting less and less radical, and less and less of the opinion that they alone are the proper ones to diagnose this disease in its early stages. The majority of them have finally taken what is the only proper attitude for them to take—that the clinician and the clinical examination of the patient *must* come first, and that the x-ray must be looked upon as an adjuvant, but a most important adjuvant, in diagnosis. As a result of the war, particularly, the French observers have commented on the fact that disease of the nasal passages and accessory sinuses will often cause a secondary infection in the lung which closely resembles tuberculosis.

Webb, G. B., and Gilbert, G. B. (*Journal American Medical Association*, March 12, 1922), in an excellent article, comment on this. They believe that disease of the nose and accessory sinuses is frequently found to be the cause of the development of pulmonary bronchiectasis, often mistaken for tuberculosis, and that cure

of the former will often relieve the latter. An editorial in the *Medical Record*, August 27, 1921, comments interestingly on the work of various French physicians who describe what they call pseudo-tuberculosis, due to disease of the upper air passages.

Spicer, F. W. (*Minnesota Medicine*, December, 1920), discussing the differential diagnosis between chronic gas poisoning and pulmonary tuberculosis, believes that gas poisoning may light up an old tuberculous process even one or two years after the original attack of gassing occurred. While I would not agree with him that the gassing itself, under such circumstances, had reactivated the tuberculosis, I feel that in certain instances the chronic bronchitis, and particularly the nervous exhaustion and general debility, which so frequently have followed gassing, may be and very often are, important factors in the outbreak of previously inactive tuberculous foci.

Mendelson, R. W. (*Mil. Surgeon*, July, 1921), believes that more careful bacteriological examination would reveal many mycotic and spirochetal infections which are now diagnosed clinically and treated as tuberculosis, especially in the Southern states, and when dealing with patients coming from the Philippine Islands. Fail, C. J. C. (*Tubercle*, June, 1921), discusses the general condition of broncho-pulmonary spirochaetosis, which is easily mistaken for tuberculosis.

Sewall, Henry (*The American Review of Tuberculosis*, January, 1921), takes up in a similar vein pulmonary atelectasis as a source of confusion in the diagnosis of tuberculosis. His article is an excellent one and is of distinct practical value. There is a long list of references. Stivelman, B. (*The American Review of Tuberculosis*, January, 1921), in an article based on the study of 1700 consecutive cases, discusses the following as conditions mistaken for pulmonary tuberculosis: chronic bronchitis and emphysema, cardiac conditions, nonspecific diseases of the upper respiratory tract, neurasthenia, chronic interstitial pneumonia, bronchiectasis, chronic nontuberculous lung infections, asthma, gastric ulcer, pulmonary abscess, dysthyroidism.

Cohen, M. Solis (*New York Medical Journal*, January 22, 1921), in a valuable article, calls our attention to various points which are considered to be important in diagnosis chiefly because they have been found to be of value in the past. Among others he mentions that râles alone do not prove that tuberculosis is active. He believes that there are tubercle bacilli carriers as well as typhoid and diphtheria carriers, and that too much evidence is placed upon the signs in the lungs in making a diagnosis. In a similar article (*Boston Medical and Surgical Journal*, December 16, 1920), he takes up the differential diagnosis of tuberculosis and cardiac lesions, cancer, syphilis, hyperthyroidism, and others.

References to the tuberculin reaction in diag-

nosis are conspicuous by their absence. The complement-fixation test has been and will be a distinctly laboratory procedure. In my own experience it is a noteworthy fact that the number of patients coming to me who can send in a detailed chart as to their temperature taken various times during the day is increasing; the number of patients, however, who can present a similar chart with reference to their pulse, which I personally consider to be of greater importance than temperature, is still strikingly small. The diagnosis of tuberculosis is still based on thoroughness and painstaking attention to details, particularly with reference to the human being and not entirely to the lungs.

TREATMENT.

In the treatment of this disease, as in diagnosis, very few striking advances have been made. We are plodding along the same lines as before, rather tending to emphasize rest than exercise, although not carrying rest to the extreme that some of its ardent supporters, notably Pratt and Kinghorn, would have us. Occupational therapy is proving a boon to the tuberculosis sufferer, while postural treatment of various kinds is helping out and replacing artificial pneumothorax. Heliotherapy—sunlight treatment—and treatment with artificial light are coming to be tremendous factors in various non-pulmonary forms of this disease.

Dr. D. A. Stewart of the Ninette Sanatorium, Manitoba, in a privately printed pamphlet, in 1920, discusses the various changes in treatment, and in our attitude toward tuberculosis, which have taken place during the past ten years. Stewart is one of our best writers and students on this subject. His articles are always well worth reading.

Webb, G. B., Forster, A. M., and Gilbert, G. B. (*Journal American Medical Association*, March 26, 1921), discuss the important subject of postural rest for tuberculosis. This includes lying on the affected side during sleep and as much as possible during the daytime, increasing gradually, aiming eventually to reach the time when the patient will spend twenty hours on the affected side. A small pillow placed under the ribs will increase the splinting effect. Sewall, H., and Swezy, S. (*American Review of Tuberculosis*, September, 1921), take up the same subject,—rest of the affected lung by means of adhesive strapping and a webbing belt. These are interesting and important attempts in the right direction.

Rollier, A. (*Tubercle*, March, 1921), the pioneer in heliotherapy, describes his new institution for this method of treatment with comments on the results obtained. Hyde, C. L., and Lo Grasso, H. (*American Review of Tuberculosis*, April, 1921), in an article delightfully illustrated, show the practical results obtained in sunlight treatment at their institution. The most important article of all on heliotherapy is

that of Edgar Mayer (*American Review of Tuberculosis*, April, 1921), who in a lengthy, but most excellent and thorough article, brings up to date the entire subject of sunlight and artificial light therapy, with an elaborate and complete bibliography of some 400 references. He urges great care in the use of sunlight in pulmonary cases and cautions against becoming too enthusiastic because of isolated success, or the reverse because of personal failures. Exposures to sunlight should be accommodated to the patient; no general theory can be followed for all cases. Treatment should be given under the guidance of a physician. In regard to artificial light, he does not feel that there is very much scientific evidence of the benefit to be derived from this source as yet. He believes that eventually the use of artificial light will be by the quartz lamp. Anyone interested in this subject will find every reference in this article.

OCCUPATIONAL THERAPY.

The subject of occupational therapy in tuberculosis is such a large one that little comment of mine is necessary. Anyone interested in this subject I would refer either to the National or to the Massachusetts Association for Occupational Therapy, and to the recently published journal, *The American Review of Occupational Therapy*. Occupational therapy as a means of aiding the physical and mental attitude of the tuberculosis sufferer and as a help to his disease, has come to stay. It is one of the splendid advances which has been brought about by the exigencies of the war. At the present time the number of occupational aides available is not anywhere sufficient, but their number is increasing, and schools for occupational therapy are developing rapidly.

Palmer, G. T., and Hoagland, H. W. (*Journal American Medical Association*, Aug. 13, 1921), discuss the tuberculosis problem which has arisen from the war, and which the federal government is trying to solve.

Hunt, F. H. (*BOSTON MEDICAL AND SURGICAL JOURNAL*, September 16, 1920), describes occupational therapy among consumptives as carried on at the Boston Sanatorium.

TUBERCULOSIS IN CHILDREN.

The subject of tuberculosis as it affects infants and young children is attracting a vast amount of attention. Wollstein, M., and Spence, R. C. (*American Journal Dis. Children*, January, 1921), discuss the subject of tuberculosis in infants and young children, based on 359 cases. C. H. Dunn and S. A. Cohen (*American Journal Dis. Children*, February, 1921) present an analysis of 374 infants in whom a diagnosis of tuberculosis was diagnosed in 12 per cent. of all admissions and confirmed in 9 per cent. Of the 374 cases, the skin tuberculin test was positive in 181; negative in 111. The high percentage of negatives is explained by the frequency of

marked atrophy and anemia. A negative Von Pirquet in no way rules out tuberculosis in an infant under two years of age, while a positive Von Pirquet at this age is sufficient evidence for a positive diagnosis of tuberculosis. They place great reliance on examination by means of x-ray.

Aehard, H. J. (*American Review of Tuberculosis*, July, 1921), a tuberculin enthusiast, believes that Nature can be helped in her process of immunization by modern science which, in plain English, means putting those children who have been exposed to tuberculosis and who have a tuberculous infection, through a course of tuberculin therapy.

A. Levinson (*Medical Record*, May 7, 1921) describes his methods in discovering and handling children with tuberculosis, and gives details of a study of 300 children. The article is of distinct, practical value, and carefully summarized.

R. M. Balyeat (*Journal American Medical Association*, April 9, 1921) presents his conclusions in regard to the diagnosis and significance of enlarged glands at the root of the lung. This article, which stresses the value of D'Espine's sign, is of interest in view of the fact that certain signs and symptoms attributed by the author to tuberculosis, and in his opinion indicative of tuberculosis of the bronchial glands, have been proved to be of comparatively little value by the recently published report of the committee on this subject of the National Tuberculosis Association.

R. S. Berghoff (*Annals of Medicine*, July, 1920) discusses the various etiologic factors in tuberculosis. Among others he considers childhood infection by means of milk and other sources, and the effects of measles, whooping-cough and other contagious diseases of childhood, and in adult life, influenza.

Henry D. Chadwick (*American Review of Tuberculosis*, February, 1921) makes a plea for the early, adequate and aggressive treatment of the tuberculous child, and particularly the child exposed to tuberculosis, as a means of reducing the present mortality and incidence of tuberculosis.

The recently published report of the committee appointed by the National Association a year or so ago to report on what constitutes the normal chest of the child, from the clinical and x-ray point of view, is of the greatest value in this connection, and should be read and studied carefully by everyone who attempts to make a diagnosis of tuberculosis of the bronchial glands or of pulmonary tuberculosis in childhood.

PATHOLOGY AND BACTERIOLOGY.

In this connection the subject of reinfection in tuberculosis is an important and much discussed one. E. R. Baldwin and L. F. Gardner (*American Review of Tuberculosis*, August,

1921), in a long and elaborate article, take up this subject, concluding their remarks as follows:

"To sum up our study of this problem, we believe that the lesson to be learned and applied is that, hand in hand with efforts to safeguard the young from infection, more attention should be paid to safeguarding both young and old from disease.

"Without sputum and dairy hygiene the supply of dangerously infected young people will be kept up; without earlier diagnosis, education, and favorable conditions of life for the prospective victims, clinical tuberculosis will continue at an irreducible minimum."

D. A. Stewart (*Nurses' Alumnae Journal*, *Winnipeg General Hospital*, 1920), writing in his usual clear style, discusses the general subject of infection in tuberculosis with practical points concerning the disease. This article is of distinct value not only to nurses but to physicians as well.

J. G. Van Swaluwenburg and G. P. Grabfield (*American Review of Tuberculosis*, June, 1921), in two articles, take up the rôle played by the tonsil in infection in tuberculosis, particularly in regard to apical pleuritis. They believe that a common route of infection to the apices of the lung may lie through the tonsils and cervical lymphatics. While this theory cannot be accepted, at present at least, without further study, it is of distinct interest.

Rhodes, W. L. (*New York Medical Journal*, December 4, 1920), as a result of his work in the army, firmly believes that there is a connection between diseased tonsils and pulmonary tuberculosis, and claims that markedly beneficial results are obtained when tonsillectomy is performed during the initial stages of the disease.

H. L. Barnes (*American Review of Tuberculosis*, October, 1921) analyzes a large number of cases with regard to the transmission of tuberculosis from the tuberculous wife to the husband, or *vice versa*. His conclusions are sound, particularly coming as they do at a time when the majority of observers feel that adult infection, at least among healthy adults, is rare:

1. "The histories of 229 consecutive widowed patients admitted to the Rhode Island State Sanatorium, 1905 to 1921, show that 93, or 40 per cent., lost their consorts by death from tuberculosis, a tuberculosis mortality over three times that of the married people of the community.

2. "Immunity from many diseases is short-lived, and until much more convincing evidence of permanent immunity against tuberculosis conferred by childhood infections is forthcoming, a cautious logic will not accept the confident statements that are being made as to the impossibility or rarity of adult infection."

TUBERCULOSIS AND INFLUENZA.

M. Fishberg (*American Journal Medical Science*, March, 1921), in taking up the much

mooted question of an influenza and a subsequent developing tuberculosis, discusses the various lung and respiratory infections and pathological conditions following influenza. He is still the champion of the comparatively few who believe that influenza had little or no effect in reactivating a tuberculous process in the lungs.

J. B. Hawes, 2nd (BOSTON MEDICAL AND SURGICAL JOURNAL, November 18, 1920), discusses tuberculosis and influenza, based on the experience of Massachusetts State Sanatoria (approximately 2000 cases) during the epidemic. He believes that the treatment of the tuberculous patient with influenza is the same as that of the person without tuberculosis, and that such a case should be regarded as a very serious but by no means a hopeless or fatal complication. Post-influenzal bronchitis and debility are real clinical entities, but in many cases serve merely to disguise a newly awakened tuberculosis. Care, conservatism and common sense are needed more than ever in handling this problem.

J. J. Singer (*American Review of Tuberculosis*, December, 1921) takes up the differential diagnosis between pulmonary tuberculosis and post-influenzal infections. He is of the opinion, and it is undoubtedly a correct one, that many patients are called tuberculous who have really a post-influenzal infection.

Finally, Heise, F. H., in the Thirty-Sixth Annual Medical Report of the Trudeau Sanatorium, 1920, takes up this entire subject, based on reports received from over 2500 discharged patients from the Trudeau Sanatorium with reference to influenza and their tuberculous processes. This is an important and might well be called a final article on this subject.

X-RAY.

It is satisfactory to note that the x-ray man and the clinician are gradually getting the same point of view and coming closer together in their work. The roentgenologist of the present day who believes that the clinician should be thrown into the discard, and that he alone is the proper person to diagnose tuberculosis, is, I am thankful to say, conspicuous by his absence.

F. W. O'Brien (BOSTON MEDICAL AND SURGICAL JOURNAL, December 16, 1920), in discussing the value of the x-ray, claims that in the majority of cases it reveals a more extensive lesion than is found by physical signs, and that it will show glandular changes before evidence of this can be found by percussion and auscultation.

With this I am in hearty accord.

Ornstein, G. G., and Sampson, H. L. (*American Review of Tuberculosis*, December, 1921), discuss the signs of activity of a tuberculous process as indicated by the x-ray. They summarize their findings as follows:

"1. Activity is indicated in the roentgenogram by (1) mottling with decidedly ill-defined margins, blending gradually with the surrounding lung tissue, which appears hazy and

cloudy (non-walled-off tubercles), and (2) the presence of spontaneous and localized pneumothoraces.

"2. The amount of activity is dependent upon the area of surface drained by the circulation (coalesced or disseminated tubercles).

"3. Diminished activity runs parallel to the amount of fibrosis and calcification that has taken place."

Although this report is interesting, I believe that it still remains, and will always remain, for the clinician to decide this important point as to whether or not the disease is active or inactive.

Amberson, J. B., Jr. (*American Review of Tuberculosis*, November, 1921), has given the final word in the etiology of the roentgenographic pleural annular shadows in pulmonary tuberculosis. His views in regard to this much disputed point are now very generally accepted.

NON-PULMONARY TUBERCULOSIS.

The x-ray treatment of tuberculous glands still has some ardent advocates. M. Berry (*British Journal Tuberculosis*, January, 1921) is one of these, and in an interesting article discusses the various methods of treatment, especially that by means of the x-ray. Bogardus, F. B. (*American Journal Ophthalm.*, September, 1920), believes that tuberculosis is the most common cause of recurrent retinal hemorrhage, and gives the details of ocular tuberculin treatment. Stark, H. H. (*Journal American Medical Association*, October 2, 1920) discusses this same subject.

R. H. Miller (article to be published in *Journal American Medical Association* later), in an excellent paper, summarizes the best accepted ideas as to the treatment of tuberculous cervical adenitis. This was read at the last meeting of the American Medical Association. I feel that Dr. Miller's work has covered this ground thoroughly and well.

EDUCATIONAL.

It is a well-known fact that the weakest link in our educational campaign against tuberculosis is that the subject is given either no or scant attention at our best medical schools in this country. Cummins, S. L. (*British Journal Tuberculosis*, July, 1921), discusses this subject in detail; Klotz, W. C. (*American Review of Tuberculosis*, November, 1921), describes how such training is carried on in the University of Virginia in affiliation with the new tuberculosis sanatorium recently established by the State Board of Health. In view of the fact that undergraduate instruction in tuberculosis, which even approaches being adequate, in the slightest, is extremely rare in the medical schools of this country, this article is of distinct interest. The same subject is taken up in a pamphlet issued by the Ohio State Sanatorium, Mt. Vernon, Ohio, describing courses in tuberculosis conducted throughout the year for physi-

cians and surgeons by the Ohio State Sanatorium. Krause, A. K. (*American Review of Tuberculosis*, November, 1921), in his usual happy and philosophic vein, takes up this same problem.

It is a curious, and to me a somewhat incomprehensible fact, that while there are special departments for syphilis, tropical diseases, and others, there are almost no special departments of tuberculosis in our medical schools, and remarkably little training in this subject. This is a state of affairs that cannot last much longer. H. Gauvain (*British Journal Tuberculosis*, January, 1921) urges that there be more thorough, systematic and prolonged training of physicians in the prevention of disease, and particularly tuberculosis, in the medical schools. He states that neither in England nor in Ireland is there a single professor of tuberculosis in any teaching school, and only two appointed in the United Kingdom. Few, if any, medical students enter any of the special institutions for tuberculosis, except as patients. The same applies to the United States just as much as it does to England. At the present time, the number of medical schools which give systematic and thorough teaching in tuberculosis, and which offer facilities for the medical student to have anything but fleeting glimpses of the early cases, and which give to their students any knowledge whatsoever of tuberculosis as a social, administrative, state and national problem, are conspicuous by their absence.

The work of the Framingham Demonstration is too well known to require much comment. Armstrong, D. B. (*American Review of Tuberculosis*, February, 1921), in an interesting article, summarizes what has been accomplished and the chief lessons that have been learned as the result of the four years that the Framingham Demonstration has been carried on. The article is well worth reading by all those interested in tuberculosis from the public health and social standpoint. The last paragraph sums the subject up briefly and well:

"In conclusion, there must be emphasized the necessity for recognizing the comprehensive nature of an effective antituberculosis program. It is essential to employ all of the community's resources. Tuberculosis is not merely a medical problem; it is not merely a health problem; it is a social problem, in the broadest sense, requiring a comprehensive community engineering plan, if the possibilities for disease control are to be realized to the full."

R. Bosworth (*American Review of Tuberculosis*, March, 1921) describes what has happened to the patients discharged from the Minnesota County Sanatoria. He believes that institutional care and control of tuberculosis will not be reached until each case is admitted before the sputum becomes positive, and, of more importance, a proper solution is found for the control

and supervision of the positive sputum case after discharge.

Billings, B. W. (*Boston Medical and Surgical Journal*, September 16, 1920), who has conducted various detailed tuberculosis surveys, in this article describes the methods which she has used and the value of such surveys.

Wagner, H. S. (*Boston Medical and Surgical Journal*, September 16, 1920), reports on the work he has been doing at Barnstable County, Mass., in itinerant consultation service. This method of bringing the doctor, expert in his particular line, to his patient, or to groups of patients, instead of the patient coming to the doctor, is proving to be a real factor in discovering cases of tuberculosis which otherwise would be missed.

MISCELLANEOUS.

Winslow, C.-E. A., and Greenberg, L. (*Journal Industrial Hygiene*, January, 1921), discuss the methods and means of controlling factory dust, the incidence of tuberculosis when under exposure to various varieties of dust and reasons why this incidence and mortality is high in some cases and less in others.

Taylor, H. L. (*American Review of Tuberculosis*, June, 1921), shows as a result of his investigations that tubercle bacilli are transferred to eating utensils and that they are potentially exceedingly dangerous avenues of contagion. He believes that public health officials should enforce the use of steam and hot water in all hotels, restaurants, and soda fountains, otherwise he believes that these public eating and drinking places must, to a certain degree, be responsible for the dissemination of all infectious diseases of the air passages and lungs and of other constitutional and general diseases.

PROGRESS IN UROLOGY.

By PAUL THORNDIKE, M.D., BOSTON,
Surgeon-in-Chief, Boston City Hospital,

AND

HERBERT H. HOWARD, M.D., BOSTON,
Out-Patient Surgeon, Boston City Hospital.

The Young-Stone Operation for Urethrorrectal Fistula.—Davis emphasizes the importance of suprapubic drainage, closure of the urethral fistula and the bringing together of the fascia and levator fibers in the middle line, thereby forming a barrier between the urethra and rectum. The operation itself is practically the same as the old Whitehead operation for hemorrhoids, that is, a cuff of the rectum is freed and pulled down far enough so that the amputation may be performed above the fistulous opening. He claims that the less extensive procedures are chiefly accountable for the numerous

failures in these cases and also goes on to state that the Young-Stone operation is not to be used in cases of tuberculosis or cancer.

*Focal Infections in Relation to Submucous Ulcer of the Bladder and to Cystitis.*²—Meisser and Bumpus at the Mayo Clinic have worked out very thoroughly and scientifically what seems to be a proof of bacterial specificity in these cases. They have shown that infection of the urinary bladder, which has often been attributed to pyelo-nephritis where no evidence at the time of infection of the kidney or where no perivesical disease was in evidence,—the real cause of the bladder infection did not come from the kidney at all. Under certain conditions the infecting organism may cause a generalized cystitis or the inflammation may become localized in one area of the bladder, causing an ulcer such as Hunner described as a "submucous ulcer." They also claim that the tissues in submucous ulcers indicate a blood-borne infection. By recent experimental investigation they have shown that pyelo-nephritis may often be due to focal infections harboring streptococci which have selective affinity for the urinary tract, and that the colon bacillus, which is commonly found and generally believed to be the cause, is one of secondary importance. They have shown that intravenous injections of colon bacilli seldom result in the production of localized urinary lesions; that after other bacteria have been injected, resulting in lesions of the urinary tract, the colon bacillus is frequently found as a secondary invader.

If the theory that vesical infections are of hematogenous origin is correct, it is natural to attribute the source of infection to oral sepsis. Hunner, in his work on submucous ulcers, has suggested this as the source of infection. They report fifteen cases of submucous ulcers done at the Mayo Clinic in which seven had had tonsillitis, three tonsillectomies, five gripes, three scarlet fevers, and two rheumatisms. Eleven patients showed evidences of periapical infection. All of these infections were associated with streptococci. Certain strains of streptococci seem to have a much greater selective affinity for the urinary tract than others.

*Thomas and Pfahler Describe a Treatment of Carcinoma of the Bladder and Prostate by a Combination of Surgery, Electro-Coagulation, Radium Implantation and Roentgen Ray.*³—Their first procedure consists of the usual routine suprapubic cystotomy and with a good exposure begin the process of electro-coagulation. They use d'Arsonval current because of the great concentration of the current at the bulbous electrode which is introduced into the bladder. There is rapid destruction or coagulation of the tissue to which it is applied. They use a current from 500 to 1,500 milliamperes. The growth in the bladder in this way is carefully destroyed and the coagulation occurs with such rapidity that there is practically no hemor-

rhage, care being used not to scald or macerate the wall of the bladder. The tumor tissue, after it has been thus destroyed, is curetted away. After the bladder has been properly irrigated the radium needles are then implanted. The needles used contain 10 milligrams of radium element each. These needles are left from eight to eighteen hours, depending upon the probable degree of malignancy. The smaller the area of disease and the closer the needles, the shorter the period of time the needles are allowed to remain. The process of sloughing which follows requires from three to four weeks. If the carcinoma involves the prostate gland the radium is used through a suprapubic wound and also by the perineal route after the method described by Herbst. They believe that roentgen-ray cross-fire is of advantage and should precede operative measures and by this treatment destroy outlying carcinomatous foci in the lymphatics. They also believe that it is of distinct advantage in postoperative treatment as well, and that this treatment should cover the entire pelvic area and extend up as far along the line of lymphatics as the condition has traveled.

*A Procedure for the Cure of Prostatic Abscess.*⁴—Barringer reports a cure of fifteen consecutive cases of prostatic abscess by a procedure much simpler than the radical method. With the patient in the lithotomy position and with the gloved index finger of the left hand in the rectum as a guide, he proceeds with local anesthesia and a 3½ inch, 18 gauge needle. Anesthetizing as he goes along, the needle is thrust into the lobe of the prostate where the abscess is localized and with a 5 cc. syringe attached to the needle suction is applied and the pus aspirated, the needle being moved backwards and forwards and also rotated so that all the pus may be aspirated from the cavity. Each lobe of the prostate is punctured, and if there is any question of a supraprostatic abscess or abscesses of the seminal vesicles, these are likewise aspirated at the same time. He advises the use of a needle similar to the lumbar puncture needles. Abscesses of the prostate caused by streptococcus, staphylococcus, or colon bacilli do not respond well to this type of treatment.

Geraghty, in Volume 7, No. 5, of the *Journal of Urology*, gives a New Method of Perineal Prostatectomy Which Insures More Perfect Functional Results, by avoiding injury to the membranous urethra and external sphincter. With the patient in the usual exaggerated perineal lithotomy position he uses the prostate retractor devised by Freiberg with the symphysis as a fulcrum forcing the prostate forwards towards the perineum. With a semicircular incision the ischio-rectal fossae are opened and a bifid retractor introduced and with retraction the central tendon becomes very tense and prominent. This is divided close to the bulb, thus exposing the rectum. Fibers of levator ani are then separated in the mid line in the re-

gion of the apex of the prostate. The anterior fibers pushed laterally while those covering the body of the gland are pushed backwards exposing the glistening visceral layer of Denonvilliers fascia. At no time during this operation is the membranous urethra exposed or is the musculature disturbed. The remainder of the operation is similar in technique to that described by Young and Himman.^{5,6}

*Treatment of Pyelitis.*⁷—Kretschmer, in his report of 200 cases of pyelitis not of a surgical nature, shows that, by a combination of pelvic lavage, together with a careful study of the case in an endeavor to find out the source of the infection, he has obtained very gratifying results. He uses, as a routine, silver nitrate irrigations and in recurring cases he has shown that the cause of the recurrence is due to the fact that the original source of infection had not been entirely removed or was impossible to be removed.

*The Formation of a Cloaca in the Treatment of Exstrophy of the Bladder.*⁸—There have been seventy-two cases of this type at the Mayo Clinic, thirty-six operated on and twenty-nine successful operations. In the early cases the Maydl and Moynihan operation was employed; an artificial cloaca was formed by making an opening between the bladder and the anterior rectal wall. The most recent cases in this group of thirty-six were operated upon by the Coffey operation of transplanting the ureters into the sigmoid by a two-stage operation and complete cystectomy with closure of the wound by fascia as the third and last stage. He also emphasizes the two dangers in this operation: First, peritonitis on account of the fact that it is an intraperitoneal operation, and, secondly, the danger of ascending pyelitis from the bowel. He states that the best time for operation is between the fifth and tenth year.

*Stenosis at the Internal Meatus after Suprapubic Prostatectomy.*⁹—Fullerton describes the stenosis occasionally resulting at the vesicoprostatic orifice following prostatectomy. Certain of these cases develop within a short period of time after the prostate has been removed; others develop at a much later period, and it is found almost impossible to pass any type of instrument or catheter into the bladder even though the patient seldom complains of difficulty in micturition. In one case it was necessary for the author to do a suprapubic exploration of the bladder in which a tent-like membrane was found almost completely covering the bladder cavity, the bladder outlet having contracted down to a very small opening. To prevent recurrence of this condition the author makes an incision through the vesicoprostatic septum. When this condition is suspected the patient should be treated with urethral dilators for some period of time.

*The Use of Gum-Glucose Solution in Major Urological Surgery.*¹⁰ The authors emphasize

the importance of a decrease in the blood pressure as a sign of beginning shock. In forty of their cases they claim to have maintained the blood pressure by the use of intravenous gum-glucose solution. It was introduced into the vein not faster than 25 c. cm. in five minutes, according to the body weight. This was followed by a maintenance of blood pressure, increased diuresis, increased thirst, the absence of nausea and increased passage of flatus. The solution has no haemolytic or agglutinative action. There were no deaths among the patients who were treated in this manner.

*A New Method of Treating Retention of the Testicle with Short Spermathe Cord.*¹¹—Sievers in this operation believes that in all cases where the testicle cannot be brought down into the fundus of the scrotum without tension on the cord, that the course of the cord should be shortened. He then describes a method of changing the course of the cord by bringing the cord down through the median segment of the obturator foramen. This type of operation removes the cord completely from the inguinal region; and he also suggests that it is a good procedure in those cases of radical operations for inguinal hernia in which, on account of the size of the hernia or recurrence, adequate closure of the abdominal wall is difficult.

*The Transperitoneal Approach to the Kidney, Its Indications and Limitations.*¹²—The author brings out the fact that this method of approach to the kidney, so far as recent text-books on urology are concerned, would lead one to believe that the method is becoming obsolete. He very forcibly emphasizes the value of this means of approach to the kidney and recommends it in renal tumors of considerable size in which the possibilities of infection have been ruled out. It not only makes the approach to the renal vessels much easier, but it also minimizes hemorrhage, which is bound to occur, to a greater or less extent, in tumors approached by the lumbar route.

*Prostatectomy Cases, Postoperative Treatment.*¹³—The author considers postoperative hiccough as a serious condition which should be checked promptly before it reaches the pernicious stage. He believes that pyelo-nephritis is a most probable cause of hiccough and that this produces a reflex or toxæmia, usually without uræmia. His treatment consists of stomach washings with $\frac{1}{2}$ per cent. bicarbonate solution two or three times daily. The administration of 2,000 to 3,000 c. cm. of a $\frac{1}{2}$ of 1 per cent. soda bicarbonate plus 5 per cent. glucose solution during each twenty-four hours, preferably by rectum by the drip method, 5 gr. of chloroform, atropine in 1-100 gr. doses every two hours for four injections, and morphine. He also believes in giving some very drastic purgative prior to the operation. Rosengerantz also prefers spinal anaesthesia, believing that it lessens the danger of hemorrhage and uræmia. He

states the causes of rise in temperature are due either to constipation, infection in the pre-vesical space, pyelo-nephritis, or a flaring-up of some old focus of infection.

*An Original Method of Observing the Kidney without Pneumoperitonæum.*¹⁴—To increase the visibility of the kidney, which is outside the peritoneal cavity, Carelli produces an artificial emphysema in the surrounding celluloadipose tissues. This is done in the following manner: A roentgenogram having been made with metallic landmarks on the skin, a fine platinum needle from 10 to 12 cm. long is inserted under strict asepsis as far as the transverse process of the second lumbar vertebra. When the process is reached the course of the needle is deviated so as to avoid the process. Oscillation of the manometer of the injecting apparatus indicates when the needle is embedded in the perirenal adipose tissue. The gas to produce the artificial emphysema is then injected in quantities ranging from 200 to 600 c. cm. Carbon dioxide is best for this purpose. Absorption is so rapid that if several roentgenograms are to be made they must be taken as soon as the emphysema is produced and as rapidly as possible. The slight discomfort caused by the gas disappears in less than half an hour.

Book Reviews.

Blood Transfusions. By GEOFFREY KEYNES. Oxford Medical Publications. London: Henry Frowde and Hodder & Stoughton. 1922.

Concise, practical monographs on special subjects should always be welcomed by the profession. Until this 158-page publication of Keynes no such monograph has appeared on transfusion, though Bernheim's "Blood Transfusion, Hemorrhage and the Anemias" printed by J. B. Lippincott Co. in 1917, approaches a work of this character. It is in this country that practically all the important advances in the science of blood transfusion have been made, yet it is this English publication that must be looked upon as the best monograph on the subject. Throughout the work the author pleasingly acknowledges the

American contributions and recognizes that it was members of our Medical Corps that gave the British much of their knowledge of transfusion. About 60 per cent. of the well selected references are to communications from the United States.

Keynes gives a connective lucid account of the whole subject and the problems rising from it. It is not an elaborate or very broadly conceived work, but in making any adverse criticisms it is unfair to let them weigh heavily against the value of the book in as much as criticisms largely concern themselves with omissions and discussions of newer views.

History makes all things more interesting and worth while so that the historical sketch of transfusion in the first chapter serves as a stimulus and guide for further study. The second chapter on "Hemorrhage and Shock" is perhaps the best one. The pathologic-physiology of these conditions and their treatment are admirably discussed. In the following chapter appears a presentation of the use of transfusion in blood diseases and toxemias. More information could be profitably added particularly as referable to the proper use and effects of transfusion in pernicious anemia; and the pathologic-physiology of the effect of transfusion on the oxygen capacity of the blood and factors of coagulation. One notes the omission of Y. Henderson's views on carbon monoxide poisoning. There also appears a lack of appreciation of the pathology of the marrow in benzol poisoning and thus the value of repeated transfusion in this condition is lost sight of.

The fourth, fifth and sixth chapters are devoted to "Dangers of Blood Transfusion," "The Physiology and Pathology of the Blood Groups," and "The Choice of Blood Donor." Reactions due to transfused blood usually attributed to the instability of blood when removed from the body are not clearly described or fully discussed. The physiology and pathology of the blood groups are well presented, including some excellent paragraphs on their inheritance. The form of routine test recommended for the determination of the blood group is a good one "admittedly not susceptible of the same finesse" as some others. In view of this fact as well as recognition and emphasis placed upon "the necessity for careful blood grouping in every case before performing transfusion," it is somewhat surprising not to find a more detailed description of tests, including direct tests on the blood of the patient and donor, and the character of reactions between sera and cell suspensions. The last chapter gives complete practical instructions for performing transfusion, especial emphasis being placed on a simple citrate method.

In spite of certain omissions this volume is to be recommended as superior to any other single work on the subject. It is not an exhaustive treatise as desired by those intimately acquainted

with the different aspects of blood transfusion. An expansion of this volume following further experience and mature thought would probably establish the work as one of more permanent value and embrace its usefulness. Its brevity and clarity, however, make it of true worth, especially for those wishing to obtain readily a connected serviceable account of the whole subject.

Applied Chemistry. By FREDUS N. PETERS. Phil.D. St. Louis: C. V. Mosby Co. 1922. Price, \$3.50.

This book is a very well arranged elementary chemistry, covering in a very interesting manner the important facts of inorganic chemistry and some of the more common phenomena of organic chemistry, such as lighting and lubricating fluids, fats and oils, starch, foods and their values, etc. It is written in very concise but readable style. Though intended primarily for a high school text-book, it is excellent for a household reference book of simple chemistry.

Clinical Laboratory Technic for Nurses. By ANNA L. GIBSON, R.N. Revised Edition. Boston: Whitecomb & Barrows. 1923. Price, \$2.00.

This is a much needed book, written by a nurse who has had good training and is actually doing this work. It is an excellent book for those who teach in training schools for nurses; for nurses doing laboratory work in the small hospitals which do not have regular chemists and pathologists; and for the office nurse, as it covers much of the same ground as the more elaborate works on diagnostic technic written for physicians, but in a simplified form that can be followed by one who has not had a medical training. It should be useful also to the practitioner when he wishes only the technic of tests, turning to the larger medical works when necessary for the interpretation of the findings.

The first two chapters describe the care of laboratory apparatus and the microscope, and the preparation of reagents, with many useful tables; a chapter each is devoted to urine, faeces, etc., including one on the preparation of tissue for microscopic study.

Food, Health and Growth. By L. EMMETT HOLT. New York: The Macmillan Co. 273 pages. Price \$1.50.

This book consists of a series of lectures given in California last winter by the author. It takes up the subject of nutrition in childhood from the broadest possible standpoint, and represents a digestion of an enormous amount of material. It is not written as a text or reference book, but is more especially a plea for recognition of the prevalence of malnutrition in children, and

the importance to the race in preventing it. Many statistics are quoted, and a great deal of the material is based on original work that Dr. Holt and his associates have been carrying on for some years.

The author always has written in an exceedingly clear and illuminating style, and this book is interesting from start to finish. The chapter on vitamins is an excellent digest of a difficult subject; that on caloric needs is also very good and points out especially how really little we have known covering the caloric needs of children, and upon what inadequate data much of our supposed knowledge is founded.

The Healthy Baby. (Second Edition Revised.) By ROGER H. DENNETT. New York: The Macmillan Co. 247 pages. Price \$1.25.

There is no question that the Mother's Manuals are popular and do a great deal of good. Dr. Dennett's is one of the best. The title is, however, somewhat misleading, as he includes a good deal of material relating to older children.

The book is in six sections, as follows:

1. Development and the Bodily Functions.
2. Hygiene and Training.
3. Common Ailments.
4. Care of the Special Organs.
5. Feeding and Diet.
6. Lists and Tables.

In the main, one can agree heartily with most of what Dr. Dennett says. Many pediatricists, however, including the reviewer, would not believe in giving a large baked potato daily to infants of 10 months, as the author recommends. Nor would most authorities believe in giving raw berries at the end of the second year. To the reviewer this seems utterly unsound. Despite one or two statements, such as the foregoing, to which exception might be taken, the book is sound, sensible, comprehensive and readable, and can be heartily recommended to all young mothers.

The book should do a great deal to stimulate physicians to be on the watch for malnutrition in children and to treat it correctly when they see it.

HONORARY DEGREES.

The degree of doctor of laws has been conferred by Lafayette College on Dr. Alfred Stengel, professor of medicine in the University of Pennsylvania.

At the 85th annual commencement exercises of Marietta College, Dr. Charles E. Humiston of Chicago received the honorary degree of doctor of science in "recognition of his efforts to raise the standard of the medical profession in all parts of the country."—*Science*.

THE SIGNIFICANCE OF THE INFLUENZA BACILLI.

BLOOMFIELD, A. L. (*Johns Hopkins Hospital Bulletin*, May, 1922) discusses two problems in regard to the epidemic of influenza, namely, (1) As to whether the influenza bacillus was the cause of the epidemic, and (2) if not, what relation did it have to the disease and what is its general significance?

He has taken up the following questions:

1. The comparative incidence in the population at large during epidemic, post-epidemic, and later periods.
2. The seasonal variation, if any, through the year in relation to respiratory disease.
3. The relative number of chronic and of temporary carriers.
4. The localization of organisms in carriers in relation to persistence.

The summary of the literature brings out the following points in regard to carriers of influenza bacilli:

(1) Influenza bacilli may be carried for prolonged and indefinite periods of time by individuals affected with chronic respiratory disease—bronchitis, bronchiectasis, lung abscess, etc. In this case the organisms seem to live and multiply in the focus of infection whence they are discharged.

(2) Normal (clinically well) people without any recent history of respiratory disease may harbor influenza bacilli in the throat. While the observations on record are few, it appears that such a carrier state may be brief or prolonged, and that in some cases the same strain of organism may be present for months or a year.

(3) Great variations have followed the experimental introduction of influenza bacilli in man. In some cases the organisms were promptly eliminated, in others a carrier state was set up lasting for weeks or even months. The situation is complicated by the doubtful relation of some of the cases to acute respiratory infection, by the fact that no exact observations were made on the location of the organisms in the upper air passages, and by the fact that in some cases old laboratory strains and in others freshly isolated human strains were used.

The main results of his present work may be briefly summarized as follows:

"In the first place it appears that the general incidence of influenza bacilli in the throats of healthy people has declined greatly since the time of the pandemic, the present figure being comparable to that which existed before the wave of influenza in 1918. Furthermore, there seems to be no striking relationship to the season of the year or to the prevalence of minor respiratory infections. An outstanding feature of the carrier state in the individuals we have observed was its usual relatively brief duration and the absence of evidence in the case of healthy people of localization of influenza bacilli in a localized area of diseased tissue such as the tonsil."

Finally, he concludes that we have in the case of the influenza bacillus group, organisms which show a marked variation at various times in their adaptation to growth on human mucous membranes. A

variety of altered conditions, especially acute infectious diseases, may produce this change but epidemic influenza does so to an extreme degree. [J. B. H.]

ORAL SEPSIS AND SYSTEMIC DISEASE.

WALSON, W. B. (*The Practitioner*, June, 1922) discusses the various conditions which in his opinion may be associated with and indeed are the result of oral sepsis. These conditions include practically all the diseases known to man. He takes them up under the diseases of the cardiovascular system, diseases of the blood and ductless glands, diseases of the digestive, nervous, respiratory and urogenital systems, diseases of the eye and the rheumatic group of diseases. [J. B. H.]

THE RELATION OF NUTRITION TO TOOTH DEVELOPMENT AND TOOTH PRESERVATION.

MCCOLLUM, SIMMONDS and KINNEY (*Johns Hopkins Hospital Bulletin*, June, 1922) presents the first part of an elaborate study of gross maxillary and dental defects in 220 rats on defective and deficient diets. Their conclusions so far are as follows:

The percentage of oral defects was greatest in rats fed the diets deficient in protein, calcium and fat-soluble A. The rats on diets low in calcium exhibited the next highest incidence and those on diets low in both calcium and fat-soluble A had the third percentage of damage.

A deficiency of the anti-scorbutic substance from the diet of man would no doubt be a factor in the production of oral disease but the rat is able to synthesize this substance.

Polyceratitis, xerophthalmia and scurvy are outspoken expressions of deficiency disease, which, in this country, fortunately are rarely encountered.

It is our belief, however, that severe oral disease may result from diets which are only relatively defective, where the disturbance appears to be out of all proportion to the cause.

In these border-line phases, the dietary defect or deficiency is minute and can only be determined by careful scrutiny of the diet and patient, or of the animals over a considerable period.

It is not possible at this time to name any one deficiency which specifically causes dental or oral disease; it would appear that any slight variation in the American diet, which always so dangerously approaches the level of dietary deficiency, might become active at any period of lowered resistance or of physical or nervous stress. [J. B. H.]

STUDIES IN ASYMPTOMATIC NEUROSYPHILIS.

MOORE, J. E. (*Johns Hopkins Hospital Bulletin*, July 1922) in this paper discusses the classification, treatment and prognosis of early asymptomatic neurosyphilis, presenting the following conclusions:

1. It has been shown that early invasion of the central nervous system in syphilis is common, occurring in 26.1 per cent. of a series of 352 patients with primary and secondary syphilis. Of 94 early neurosyphilis, 72 were asymptomatic, and were detected only by the routine application of spinal puncture.

2. Early asymptomatic neurosyphilis may be divided into three sub-groups on the basis of the spinal fluid findings and the response of the various groups to treatment.

3. Invasion of the central nervous system probably occurs in the majority of all patients with syphilis, and unless the course of the disease is influenced from without (by treatment), this invasion takes place in most instances within the first year after infection. The ability of the invading organisms to produce clinical neurosyphilis probably depends on the defense mechanism of the individual patient. The experimental and clinical evidence bearing on these points are reviewed.

4. Early asymptomatic neurosyphilis is more common in the white race than in negroes, but is equally frequent in men and women, of either or both races.

5. Prolonged regular treatment influences favorably the incidence of early asymptomatic neurosyphilis. Irregular or lapsing treatment, on the other hand, markedly increases its incidence.

6. A study of this material from the standpoint of strains of *Treponema pallidum* furnishes no support to the theory of the existence of a neuroptic strain of organism.

7. That the spinal fluid abnormalities of early asymptomatic neurosyphilis are evidence of actual anatomical damage to the nervous system, is indicated by the frequency of certain minor subjective and objective neurologic signs in this class of patients. An appreciation of these signs, and of the significance of a persistently positive blood Wassermann reaction in treated patients, furnishes a clinical diagnostic aid for the recognition of neurologic invasion.

8. Spinal puncture is an indispensable routine procedure in the management of early syphilis. Unless it is employed, many patients will be discharged as cured who are nevertheless candidates for clinical neurosyphilis. It should be performed as a routine after the first or second course of arsphenamin, and unless a lapse in treatment occurs, need not be repeated (if negative) until the end of treatment and the probation period.

9. All three groups of asymptomatic neurosyphilis may be serologically and clinically "cured" by appropriate methods of treatment.

10. Early asymptomatic neurosyphilis is the forerunner of clinical neurosyphilis. One patient of our second group has developed clinical cerebrospinal syphilis. Of the third group, three patients have developed general paresis and one cerebrospinal syphilis.

11. There is suggested an outline of treatment for early syphilis, the uniform application of which will markedly reduce the incidence of asymptomatic neurosyphilis, and probably, therefore, of clinical neurosyphilis. [J. B. H.]

THE BIOCHEMISTRY OF TUBERCULOSIS.

LONG, E. R. (*Johns Hopkins Hospital Bulletin*, July, 1922) discussing the complex subject of the biochemistry of tuberculosis concludes as a result of his investigations and of others that in progressive tuberculosis the rate of metabolism is increased, as a result of the operation of two factors, hyperthermia and the toxic effect of a foreign protein upon protoplasm. As far as protein destruction is concerned, the second of these seems to be the more important, for hyperthermia *per se* does not increase nitrogen elimination in the normal subject. Yet it may well be that in the increased general metabolism induced directly by fever, the tissues become impoverished in those protein-sparing constituents which serve to prevent protein destruction at similar temperatures in health, and that protein may for this reason be drawn upon to maintain the high level of total energy transformation. [J. B. H.]

THE ETIOLOGY AND TREATMENT OF DIABETES.

RENSHAW and FAIRBROTHER (*British Medical Journal*, April 29, 1922) discuss the significance of a starch-splitting and acetone-forming organism found in the stools of diabetic patients, summarizing their results as follows:

1. From the stools of diabetics a new organism (*C. amylobacterius infestantis*) has been isolated which splits up starchy foods, forming oxybutyric acid, diacetic acid, butyl alcohol, and acetone. Sugar is also formed during this fermentation.

2. Acetone has been found in quantities capable of estimation in the stools of diabetics.

3. In diabetes carbohydrate fermentation occurs in the alimentary canal, forming abnormal products which probably so affect the glycogenic function of the liver as to lead to improper storage therein of the glucose from the alimentary canal during digestion.

4. Definite lines of treatment include elimination or suppression of this organism. [J. B. H.]

CALCIUM DEFICIENCIES: THEIR TREATMENT BY PARATHYROID.

GROVE and VINES (*British Medical Journal*, May 20, 1922) discussing the various conditions in which there is a calcium deficiency such as the chronic toxæmias, particularly suppurative conditions, from the clinical observations which they describe, draw the following conclusions:

1. The ionic calcium of the blood becomes deficient in cases where a chronic toxæmia is present. Such deficiency may be regarded as one of the manifestations of the presence of a chronic toxic state, and is an indication that the septic focus should be carefully sought for and treated where possible.

2. Where there are lesions due to such states, healing does not commence until the ionic calcium of the blood approximates to the normal figure.

3. By parathyroid therapy it is possible to rectify the calcium balance of the blood much more effectively than by the injection of calcium salts.

4. The therapeutic use of parathyroid substance in the cases described is essentially physiological. It does not appear to act specifically against any one organism, nor any one toxin. Its action is to place the tissues of the patient under conditions more suitable for the performance of their normal functions, and for combating the effects of toxic processes. [J. B. H.]

DYSPEPSIA AND CONDITIONS UNDERLYING IT.

DAWSON (*British Medical Journal*, June 3, 1922) divides the various forms of dyspepsia into three groups as follows:

1. Pain or discomfort thirty to forty minutes after food with epigastric tenderness. Vomiting, if present, follows the pain and relieves it. Haematemesis is an occasional feature.

2. Pain two to three hours after meals (it may be with tenderness) relieved by food and alkalis—the hyperchlorhydria complex.

3. Distention and flatulence are the dominant features, and the discomforts which go with them. Vomiting and bleeding do not occur. The bowels are liable to act irregularly and incompletely.

He discusses these groups in detail and in a plain and practical manner. His article is of distinct value to the general practitioner. [J. B. H.]

A PULMONARY SIGN IN ACUTE INFECTIONS OF THE BILIARY TRACT.

WILKIE, D. P. D. (*British Medical Journal*, June 10, 1922) believes that in certain acute infections of the biliary tract there are pulmonary signs at the base of the right lung. He believes that in a patient complaining of pain at the right costal margin and round the right side of the chest the discovery of crepitations or even of pleural friction at the right base does not preclude, but may support, the diagnosis of an acute biliary infection and that such pulmonary signs are secondary to the biliary infection, and, far from contraindicating operation, will be effectively treated by dealing surgically with the primary focus of disease. [J. B. H.]

SUBSCRIPTION TERMS: \$6.00 per year in advance, postage paid for the United States, \$7.50 per year for all foreign countries belonging to the Postal Union.

Material for early publication should be received not later than noon on Saturday. Orders for reprints may be sent to the printer with galley proof of paper. Upon written request, authors will be furnished free one hundred eight-page reprints, without covers, or the equivalent in pages in articles of greater length.

The Journal does not hold itself responsible for statements made by any contributor.

Communications should be addressed to The Boston Medical and Surgical Journal, 126 Massachusetts Ave., Boston, Mass.

THE TUFTS COLLEGE MEDICAL SCHOOL.

THE new era now opening in the history of the Tufts College Medical School under the leadership of the newly-elected Dean, Stephen Rushmore, will be of interest to those concerned with medical pedagogy.

This school began its work in the autumn of 1893. The first dean was Albert Nott, M.D., who served two years. He was followed by John L. Hildreth, A.B., M.D., LL.D., who served two years. Next in order was Harold Williams, A.B., M.D., LL.D., who served thirteen years. Dr. Charles F. Painter, A.B., M.D., held the office for eight years, and after his resignation there was an interim during which Dr. Frank G. Wheatley was acting dean until the appointment of Dr. Rushmore. Under the leadership of these men the Medical School grew in influence and was rated by the Council on Medical Education as a Class A school.

The professors and associate professors of the various departments at this time number 43, as follows:

Professors Emeriti — Frederic Melancthon Briggs, A.B., M.D., Surgery; Henry Beckles Chandler, C.M., M.D., Ophthalmology; Elwood Tracy Easton, M.D., Ophthalmology; John Lewis Hildreth, A.B., M.D., LL.D., Clinical Medicine; George Wharton Kean, M.D., Clinical Gynecology; Morton Prince, A.B., M.D., LL.D., Neurology; John Jenks Thomas, A.M., M.D.,

Neurology; George Hamlin Washburn, A.B., M.D., Obstetrics; Harold Williams, A.B., M.D., LL.D., Theory and Practice of Medicine.

Professors—John Lincoln Ames, A.B., M.D., Theory and Practice of Medicine; George Andrew Bates, M.S., D.M.D., Histology; William Elisha Cheney, A.B., M.D., Laryngology; Felix Percy Chillingworth, M.D., Physiology; William Robie Patten Emerson, A.B., M.D., Children's Diseases; Leo Victor Friedman, A.B., M.D., Obstetrics; Allen Greenwood, M.D., Ophthalmology; Frederick William Johnson, A.M., M.D., F.A.C.S., Clinical Gynecology; Frank Howard Lahey, M.D., Clinical Surgery; Edward Binney Lane, A.B., M.D., Mental Diseases; Timothy Leary, A.M., M.D., Pathology, Bacteriology and Medical Jurisprudence; Edward Norton Libby, A.B., M.D., Clinical Medicine; Francis Henry McCruden, B.S., M.D., Applied Therapeutics; Edward Osgood Otis, A.B., M.D., Pulmonary Diseases and Climatology; Charles Fairbanks Painter, A.B., M.D., Orthopedic Surgery; Edward Marwick Plummer, M.D., Otolaryngology; Andrew Howard Ryan, M.D., Physiology; Townsend William Thorndike, M.D., Dermatology; Frederick Wilbur Thyng, A.M., Ph.D., Anatomy; Frank George Wheatley, A.M., M.D., Pharmacology; Charles Melville Whitney, M.D., Genito-Urinary Diseases.

Associate Professors—Elmer Walter Barron, A.B., M.D., Children's Diseases; Arthur Lambert Chute, M.D., Genito-Urinary Surgery; Jesse LeRoy Conel, A.M., Ph.D., Anatomy; Walter Elmore Fernald, M.D., Mental Diseases; Frank Eugene Haskins, Ph.G., M.D., Pharmacology and Toxicology; Arthur Ronald Kimpton, M.D., Surgery; Walter Freeman Nolen, M.D., Anatomy; Thomas James O'Brien, Ph.G., M.D., Clinical Medicine; Henry Joseph Perry, A.B., M.D., Dermatology; Louis Eusebe Phaneuf, Ph.M.D., Ph.C., M.D., F.A.C.S., Clinical Gynecology; Cadis Phipps, A.B., M.D., Clinical Medicine; Stephen Rushmore, A.B., M.D., Gynecology; Frank Percival Williams, M.D., Surgery.

In addition there are over a hundred assistant professors, instructors, teachers and laboratory assistants.

During its existence the Medical School has conferred the degree of Doctor of Medicine on 1764 graduates. There were 441 students in the school last year and about 140 will enter this year.

The Dental School, formerly the Boston Dental College, became a part of Tufts College in 1899. The buildings are two in number, consisting of a main building occupied by the Medical and Dental schools, with seven lecture rooms. There are well-equipped laboratories for general work and instruction and an equal number of private research laboratories.

Although the students have access to the public exercises in the hospitals of Boston and

many secure positions in out-patient and house services, a large hospital directly controlled by this school would add to a great extent to the teaching facilities. The creation of such a hospital or close affiliation with one will come in time.

The graduates of Tufts Medical School have played an important part in the medical history of this section of the country and this institution is bound to meet many of the demands for practitioners of medicine.

The BOSTON MEDICAL AND SURGICAL JOURNAL extends its hearty good wishes to Dean Rushmore and for the future progress of the Tufts College Medical School.

FULL-TIME TEACHERS IN MEDICAL SCHOOLS.

IN an address delivered at the Seventeenth Commencement Exercises of the Woman's Medical College of Philadelphia Professor Florence R. Sabin closed with the following:

"I may say that I do not think that all the problems associated with the practical extension of the full-time scheme to the clinical side have been solved. Adjustments may have to be made, perhaps radical ones, but I profoundly hope that the plan will be given an adequate trial and that it can win the support of those who are teaching in our medical schools, because I believe it of the utmost importance to the community to range the ablest minds in the medical profession on the side of preventive medicine. Besides an occasional school of hygiene and public health we need to have all the leaders of medical education engaged in research to advance medicine. It is my sincere conviction that the opposition to extending the modern standards of professional education to clinical medicine will yield readily to sound constructive leadership on the part of those who desire this reform."

This subject of full-time teachers in medical schools has been under consideration for several years. Prominent practitioners and teachers have discussed the subject from every angle, but without unanimity of opinion. Practically everybody is agreed that the laboratory sciences require full-time teachers, but since medicine is to a considerable extent an art founded on the sciences, one may question whether the clinical teaching may not lose some of its interest if given over to men working full time in hospitals and laboratories. The time may come when Public Health executives may practically eliminate the preventable diseases and the exact sciences may be applied to the cure of a larger number of ills, but at the present time the experience gained from contact with some of the unsolved problems of medicine and the psychic phenomena of diseased persons may equip the teacher for dealing with the student's mind to

some extent not otherwise obtained. The advocates of the full-time teaching service may suggest that men of sufficient ability to warrant selection for such positions have broad minds and warm human instincts and usually understand the difficulties of practice, and hence are fitted to train practitioners, or it may be argued that premedical requirements demand of young persons that degree of moral and intellectual development which is sufficient for the practitioner and will enable him to intelligently use science so far as it may apply and supplement exact knowledge with that personal influence which the art of medicine requires. Leaving these questions out of the argument, one may propound another which may be asked concerning the wishes of the patient as well as his needs. Will the patients feel as well pleased with the ultimate division of medical attendance between two classes, *i.e.*, the purely scientific worker and teacher and the practitioner? And going one step farther, has not the teacher who is also a practitioner, outside of the medical school, often contributed to medicine some things which his colleague, devoted entirely to research teaching and hospital work, has missed?

These are questions worthy of serious consideration and analysis, and will in turn be solved. At present they are debatable.

NEWS ITEMS.

THE MEDICAL PRESS AND CIRCULAR reports the death of Dr. Charles Henry Brooking, who was born April 3, 1822.

PROFESSOR J. J. MACKENZIE, head of the pathological departments of the University of Toronto, died on August 1 at the age of fifty-seven years as a result of infection contracted during his experiment with the pus-forming bacteria.—*Science*, Aug. 11, 1922.

WEEK'S DEATH RATE IN BOSTON.—During the week ending Aug. 12, 1922, the number of deaths reported was 188, against 168 last year, with a rate of 12.83. There were 30 deaths under one year of age, against 31 last year.

The number of cases of principal reportable diseases were: Diphtheria, 42; scarlet fever, 13; measles, 35; whooping cough, 27; typhoid fever, 5; tuberculosis, 52.

Included in the above, were the following cases of non-residents: Diphtheria, 9; scarlet fever, 2; measles, 1; typhoid fever, 1; tuberculosis, 29.

Total deaths from these diseases were: Diphtheria, 3; scarlet fever, 2; whooping cough, 1; tuberculosis, 13.

Included in the above, was the following case of a non-resident: Tuberculosis, 1.

NOTES FROM THE WORCESTER DISTRICT MEDICAL SOCIETY.—Provisional arrangements have

been made for the first meeting of the society, to be held September 13. Dr. George E. Albee of Worcester will read a short paper on "Heart Disease" and will illustrate his paper with lantern slides of electrocardiograms. Dr. S. A. Levine of Peter Bent Brigham Hospital in Boston will open the discussion. The meeting will be held in the rooms of the University Club, on Main Street.

Dr. Perley Comey of Augusta, Ga., formerly a president of the Worcester District Medical Society, has opened an office for the summer in his old home on Lincoln Street, Worcester.

During the war arrangements were made by the Worcester District Medical Society to co-operate with the police in the event of any great catastrophe. The names of members who would respond to call were taken and placed on file at the telephone exchange. Fortunately no occasion to test out these arrangements had arisen until the wreck of the Berkshire Express at Putnam Lane, August 8. At the first it looked as if many people must have been injured, and the emergency call was sent out for physicians. The plan worked out during the war showed its value when between 30 and 40 physicians responded, ready to render aid.

Dr. G. W. WILLIAMSON of Grand Forks, S. D., has been visiting the hospitals and other places of interest in and about Boston.

BEVERLY HOSPITAL.—The regular monthly demonstration clinic was held at the Beverly Hospital, Aug. 15, 1922. Doctors were present from Beverly, Danvers, Hamilton, Topsfield, Lynn, Swampscott, Manchester and Beverly Farms. The following cases were shown and discussed: Carcinoma of Right Breast; Epithelioma of Right Submaxillary Gland; Acute Retention of Urine; Acute Appendicitis—General Peritonitis; Chronic Cholecystitis with Stones in Gall-Bladder, Cystic and Common Ducts; Acute Suppurative Cholecystitis—Acute Hemorrhagic Pancreatitis; Chronic Cholecystitis with Stones—Chronic Pancreatitis; Chronic Appendicitis—Chronic Cholecystitis with Stones; X-rays and Specimens.

A. EVERETT AUSTIN, M.D., announces his removal from 144 Commonwealth Avenue to the Professional Building, 270 Commonwealth Avenue (at Gloucester Street, near Massachusetts Station).

Miscellany.

AN IMPRESSIVE STATEMENT.

THE *Buffalo Sanitary Bulletin*, under date of July 31, 1922, announces under the heading "A Cure for Polio" that Dr. Edward C. Rosenow, Professor of Experimental Bacteriology of the

Mayo Foundation, claims that he has proven "the most successful" treatment for acute anterior poliomyelitis. The statement in the *Bulletin* is as follows:

Dr. Rosenow demonstrated that the serum of a horse, which had been immunized with streptococci isolated from the central nervous system of monkeys paralyzed with virus, had the power to neutralize virus *in vitro*, and to prevent poliomyelitis in monkeys following intracerebral inoculation of active virus. Moreover, this serum appeared to have a curative effect in the experimental disease in monkeys after the symptoms had begun.

Opportunities to test this serum were found during the epidemic in Davenport, Iowa, in 1917, and Dubuque, Iowa, in 1918, and have been used since in sporadic cases by physicians in various parts of the United States.

A summary of results showed that of 60 patients in whom this serum treatment was begun early, every one recovered without paralysis; of 61 patients with slight paralysis at the time of serum treatment, all but one recovered without residual paralysis; of 123 patients with advanced paralysis at the time of serum treatment, 18 died; 30 recovered from residual paralysis; 61 made complete recovery; while the results of the remainder are unknown.

Dr. Rosenow states:

"The conclusions that my Immune Horse Serum, prepared by repeated injections of increasing doses of freshly isolated strains of the pleomorphic streptococcus, has curative power in poliomyelitis, especially when given in the early stage of the disease, is warranted. Its general use in the treatment of this dread disease is indicated, and the need for early diagnosis in suspicious cases by spinal puncture is again emphasized."

Our State Department of Health and the New York Department of Health maintain a conservative attitude toward claims of benefits following serum treatment of acute anterior poliomyelitis, and the United States Public Health Service has not licensed the product advocated by Dr. Rosenow. The Massachusetts Department of Health has on file telegrams relating to this subject from the United States Public Health Service and the New York Board of Health, received within a few days. Further developments will be watched with interest.

DR. J. LEO HANSON'S APPLICATION FOR HOSPITAL LICENSE REFUSED.

THE daily papers report that the citizens of West Dennis have declined to issue a permit to Dr. Hanson for the maintenance of a hospital. One paper alleged that the "transplantation of a bull gland" by Dr. Hanson caused the death of a sixteen-year-old boy. There seems to be a strong adverse sentiment toward Dr. Hanson and his methods, for a public meeting was held

and, according to the reporter for the Boston Post, 81 voted against Dr. Hanson's plan for a hospital and only seven were in favor. The meeting was attended by so many who took this opportunity to voice protests that it lasted until nearly midnight.

Dr. Hanson is a graduate of the Philadelphia College of Osteopathy and the Middlesex College of Medicine and Surgery located in Cambridge. Gland therapy has not been a distinctive feature of the practice of osteopathy, so that one may infer that either Dr. Hanson is departing from the practice of his first interest or is planning to supplement the methods of the osteopathic practitioner with treatments about which controversy has been spirited.

A NEW STAR IN THE MEDICAL FIRMAMENT.

ACCORDING to the New York Times a doctor in Munich by the use of the iriscope has told the medical history of patients to the minutest detail. He claims that the iris records injuries and diseases with unfailing accuracy. No questions are asked during the examination. In given cases the doctor found that the persons under examination had used alcohol or had had various injuries, which were located. In one instance he asserted that the patient had lost a finger. The patient remembered having cut the finger severely in an automobile accident and "what was left of the finger was sewed on and has done well."

The reporter suggests that if one decides to visit the doctor that he had better go alone. The iriscope is no place for company if you have anything which you wish concealed, for "The worst discovery of the century has come."

CONSERVATION OF VISION.

THE Eye Sight Conservation Council of America, as a result of various inquiries and requests, is establishing a special mailing list of those who wish to receive material of service to lecturers and writers on the subject of conservation of vision.

There is need throughout the nation for lecturers who will appear before local organizations and address such organizations as Rotarian and Kiwanis clubs, mothers and parent teachers' associations, chambers of commerce, merchants' associations, schools, colleges, etc., to present the important subject of eye care and the great need of conservation of vision.

Any who are interested in this work should write direct to the Eye Sight Conservation Council, Times Building, New York City, requesting that their name be entered on a special list of those to receive data and material which will be prepared and issued periodically.

RECENTLY ESTABLISHED SCHOOL OF GRADUATE TEACHING OF DISEASES OF THE NERVOUS SYSTEM.

UNDER the title of The Post-Graduate School of Neurology and Psychiatry of the District of Columbia, a school for the graduate teaching of diseases of the nervous system has been recently organized in Washington, and will open formally in October. Dr. Wm. A. White, Superintendent of St. Elizabeth's Hospital, is President of the institution; Dr. Tom A. Williams, Vice-President; Dr. D. Percy Hickling, Dean of the faculty; and Dr. Daniel D. V. Stuart, Jr., Secretary-Treasurer. Two courses of study, elementary and advanced, of six weeks each, are to be offered, together with an elective course in special subjects.

EXCERPTS FROM THE INFORMATION SERVICE OF THE ROCKEFELLER FOUNDATION.

PARTS of the annual report of the General Director of the International Health Board of the Rockefeller Foundation, made public recently in advance of the general distribution of the volume, show that during 1921 the Board shared in the governmental activities for war on preventable disease in sixty-three states and countries throughout the world.

The activities reported include campaigns against yellow fever in Mexico and South America; field experiments and operations in malaria control; world-wide efforts in the relief and control of hookworm disease; the promotion of county health work in the United States; the improvement of public health laboratory service in various countries; the development of schools of hygiene; and fellowships offered by the Board in hygiene and public health.

PROMOTING COUNTY HEALTH WORK.

"For reasons which are well understood, public health effort has been centered mainly on the larger towns and cities. Health protection for the people living in the country districts has been neglected. The tide is turning. The development of county health organization—which is now going forward with considerable momentum in the United States—is providing a service for the smaller towns and rural communities.

"In the Southern States county health administration developed naturally and inevitably from the effort to control hookworm disease. This is a rural disease; its control is a problem in rural sanitation; a serious effort to handle this one problem in rural sanitation called into being county organization. County organization once established, control of hookworm disease became merely an item in a general health

program under state and county administration. The demonstration thus given of the value of the county as a unit in the state scheme stimulated a movement which is becoming general. At the close of the year county programs on a full-time basis were in operation in about 192 counties in the United States."

"The plan of work pursued by the county health department has been evolved from experience, is applicable under a wide variety of conditions and has stood the test of time. Though there are minor differences to meet local conditions, the most important activities, which are more or less common to all the units, group themselves under the following main heads: (1) public health education; (2) sanitation; (3) control of communicable diseases; (4) adult and child hygiene. The demonstrations are so planned as to enable any county to undertake at the start in a small way and with the least expenditure of money, the line or lines of work which for that particular county give promise of yielding the greatest results in lives saved and sickness prevented. Other activities are added and the health department is expanded as the work proves effective and additional funds are provided.

"Public health nurses are being employed in increasing numbers. They furnish a close bond of contact between the health staff and the people. When a case of communicable disease is quarantined they visit the home and give advice as to the methods to be followed in caring for the patient and in preventing the spread of the disease to other members of the family or to the community; when children are found to be suffering from defects they consult with the parents and urge them to have the defects promptly corrected; and they render valuable assistance to the health officer in the organization and conduct of clinics, in securing the co-operation of established welfare agencies, and in carrying out the general program of health education and community development.

"In the development of county health work the Board has been serviceable in providing funds for initial demonstrations. Its contributions have stimulated appropriations by counties and legislatures; and the demonstrations thus supported are creating a sustaining public sentiment. The state and county appropriations usually show wholesome growth from year to year, and are seldom reduced even in the face of the severe economic depression that has necessitated curtailment of many useful forms of service."

EXCERPTS FROM THE BI-WEEKLY SUMMARY NATIONAL HEALTH LEGISLATION AS PUBLISHED BY THE NATIONAL HEALTH COUNCIL.

New Hospitals for Disabled War Veterans.—Director Forbes of the U. S. Veterans' Bureau

has announced that in accordance with the appropriation act providing \$17,500,000 in funds for new hospital sites he has recommended to the President a hospital at St. Cloud, Minn., to cost \$1,000,000, with facilities for between 250 and 350 beds for mental cases. This has received the President's approval. Another recommendation not yet approved is for a hospital at either San Diego or Los Angeles, California.

Assistant Secretary of the Treasury Clifford has announced that the appropriation of \$18,000,000 of last year authorizing hospitals to be constructed under the authority of the Treasury Department has been expended and that a total of 4,051 beds has been supplied by building additions to Government hospitals and by the construction of twelve new institutions. These hospitals include facilities for the care of disabled veterans suffering with tuberculosis and mental diseases, surgical cases and general cases.

Government Reorganization.—During a recent visit by Dr. D. B. Armstrong, executive officer of the National Health Council, with Brig. Gen. C. E. Sawyer, the latter stated that the plans for a Department of Welfare were still under consideration and that the whole Government Reorganization scheme would be taken up after Congress had gotten such items as the Tariff, Bonus, and Ship Subsidy out of the way. It is not deemed likely that the reorganization will be taken up at this session, even if the plan were entirely agreed upon, which is not considered to be the case among observers in Washington.

New Legislation.—B. 1. Amendment to Constitution Empowering Congress to Regulate Child Labor. S. J. Res. 224. Introduced by Senator Townsend, July 14, 1922. Referred to the Committee on the Judiciary. This amendment to the Constitution provides that Congress may regulate the employment and the hours of labor and conditions of employment of persons under eighteen years of age.

THE NEW YORK DAVENPORT BILL.

In introducing this bill, which afterward became a law, State Senator Frederick M. Davenport, one of the proponents of this measure, said:

"This is a bill to establish a division of maternity, infancy and child hygiene in the State Department of Health. It is designed to accomplish under state auspices, state rules, and with state funds everything of value and more which is contemplated in the alternative plan of matching the funds of the federal government with other funds of the state government under the so-called Sheppard-Towner maternity act of the national Congress.

"The state of New York, if this measure is enacted into law, formally repudiates the growing tendency of the national government to

encroach in a subtle fashion upon the functions and activities of the states. It is not denied that in matters affecting, for example, post roads and interstate commerce, the federal government is within its rights in leading the way toward better policies of national welfare. But this is a boundary which ought not lightly to be passed. And it is very doubtful whether constitutionally it can be passed. A policy which drags the state governments at the chariot wheels of the national government in a constantly increasing number of matching proposals and multiplying functions and expenditure, is fraught with ultimate disaster not only to the states but to the national government itself.

"The most certain way to keep the national government strong and vital is to protect it from too much functioning. One great danger in Washington today is that the national government may cave in under its overwhelming activities. Everything that the states can do for themselves, everything which fosters local self-government, contributes to the normal functioning and power of the national government as much as it does to the preservation of the rights and responsibilities of the states.—Excerpts from *Health Notes*, New York State Department of Health.

FOREIGNERS AS ASSISTANTS IN ITALIAN CLINICS.

ON the initiative of the Italian League for the Protection of National Interests, the Faculty of Medicine of the University of Rome has granted foreign physicians the privilege of entering the Medical and Surgical Clinics of the University of Rome in the capacity of assistants without salary—a measure which has been adopted with marked success by the universities of France.

These Roman Clinics are under the direction of the greatest Italian physicians and surgeons.

The following places are available for the next academic year, which begins in the first week of November:

- 2 places in the Surgical Clinic.
- 2 places in the Medical Clinic.
- 2 places in the Obstetrical Clinic.
- 2 places in the Dermosyphilopathie Clinic.
- 2 places in the Clinic for Mental and Nervous Diseases.
- 1 place in the Orthopaedic Clinic.

Foreign physicians are admitted also to the numerous finishing courses offered by the Medical Faculty of Rome.

Applications may be addressed to the President of the Faculty of Medicine of the University of Rome, accompanied by a certificate of graduation and favorable recommendation from the president of the applicant's medical school.

Applications with documents will be received also by the Italian League for the Protection of National Interests (Lega Italiana per la

Tutela degli Interessi Nazionali) Roma (8) Corso Umberto Primo No. 101, which will furnish all required information.—Institute of International Education, Stephen P. Duggan, Director.

EXHIBIT SHOWING ADVANCES IN SANITARY SCIENCE.

THE National Committee on Exhibits Showing Advances in Sanitary Science has recently been formed in Washington, D. C., for the purpose of collecting and preparing material for a great popular public health exhibit in the capital. The members of the committee include Surgeon-General H. S. Cumming, United States Public Health Service, chairman; Dr. D. B. Armstrong, National Health Council; Miss Mabel T. Boardman, American Red Cross; Surgeon-General M. W. Ireland, United States Army Medical Corps; Dr. Victor C. Vaughan, National Research Council; Dr. C. D. Waleott, Smithsonian Institution; James A. Tobey, National Health Council, secretary.

Space for the proposed exhibit has been placed at the disposal of the committee by the Smithsonian Institution. This Institution is visited by more than half a million persons annually. Plans are under way to install exhibit material secured from official and voluntary health agencies. The secretary's office is in the national headquarters of the American Red Cross at Washington, D. C.—*Public Health Reports*, U. S. P. H. Service.

SQUILL EFFECTIVE AS A RAT POISON.

MANY observers abroad are of the opinion that fluid extract of squills is a most efficient rat poison. It is claimed that it has thrice the toxic effect of barium carbonate and is relatively harmless to other animals and birds. It is cheap, and, since it creates great thirst, the poisoned rodents die in the open. It is prepared by macerating freshly purchased bulbs of *Urginea maritima* with alcohol 1:5 for six days and then expressed through a cloth. The baits are prepared by soaking small pieces of bread in the fluid extract. Poisoned animals are dead by the second day.—*The Nation's Health*.

ANTISCORBUTIC VITAMIN IN COW'S AND GOAT'S MILK.

C. H. HERTZ and A. R. Winter report experiments made upon guinea pigs to determine the relative value of cow's and goat's milk in the production of vitamin C. Ten c.c. of cow's milk, fed daily, did not seem to have the same protective power as an equal amount of goat's milk, but when the amount of cow's milk was increased to 30 c.c. or more daily no difference was noted. This report was published in *Science*, July 28, 1922.

ARTICLES ACCEPTED BY THE COUNCIL
ON PHARMACY AND CHEMISTRY.

During July the following articles have been accepted by the Council on Pharmacy and Chemistry for inclusion in the New and Non-official Remedies:

The Abbott Laboratories: Neoeinchophen-Abbott Tablets, 5 grains; Louis Hoos: Hoos Albumin Milk; Mallinckrodt Chemical Works: Benzyl Benzoate-M.C.W.

LOWER DEATH RATES.

THE Metropolitan Life Insurance Company reports that the death rates among the policyholders for the first half of 1922 show a drop from 10.3 per 100,000 in the first six months of 1921 to 8.1 for the corresponding period this year. The tuberculosis rate was 13 per cent. lower, the diphtheria rate was 23 per cent. lower, and the puerperal septicaemia rate dropped from 10.3 to 8.1. These figures may reflect a more general knowledge of health problems on the part of the people in addition to coöperation of physicians and health officials.

HOOK WORM INFECTION AND HOOK
WORM DISEASE.

Dr. J. A. HAYNE of Columbia, S. C., in discussing a paper on health work said: "The person carrying around a few hook worms in the intestinal canal is not particularly annoyed by them, but if he has a great many that are really sapping his vitality then he develops hook worm disease. * * * * In a certain university 70 per cent. of the students were infected with hook worm, yet they went into a football game with no difficulty."

Dr. Hayne has observed hook worm in Panama as well as in South Carolina.

A REMARKABLE MEDICAL MEETING.

Dr. GEORGE W. PAYNE, secretary of the Carlisle County Medical Society, Kentucky, reports that the meeting of this society, June 6, 1922, was attended by every doctor in the county. Every paper on the program was read and every doctor joined in the discussion.

THE FIFTEENTH ANNUAL CHRISTMAS
SEAL SALE.

THE National Tuberculosis Association has begun its campaign for the next Christmas Seal sale. Five different styles of advertising material, stories and articles on various phases of tuberculosis health problems are described in

the circular which is being sent out by Philip B. Jacobs, the publicity director.

The great outstanding argument of the saving of 100,000 lives each year, with the conservation of a vast amount of productive energy, will be the especial feature of the campaign.

Dr. LAWRENCE BROWN is the president and Dr. CHARLES J. HATFIELD the managing director, and there are about 90 directors, representing all sections of the country.

Obituary.

WILLIAM TURELL LEARNED, M.D.

Dr. WILLIAM T. LEARNED, a well-known general practitioner of Fall River, died at his home in that city, Aug. 14, 1922, of angina pectoris, after an illness of two days.

The son of the late Ebenezer T. and Mary White Learned, he was born in Fall River, March 24, 1861. His early education was in the public schools of his native city, then going to Brown University, where he received an A.B. in the class of 1882. Three years later he took his M.D. at the University of Pennsylvania, settled in practice in Fall River, joining the State Medical Society in 1887. In 1889 he married Frances H. Elmer of Bridgeton, N. J., one son, Dr. Elmer T. Learned, practises in Fall River, another son and a daughter live in the same city.

Dr. Learned had been surgeon to the Union Hospital, consulting physician to the City Hospital, senior physician to the Truesdale Hospital; a member of the American Medical Association, the Quequechan and Country Clubs, and at one time active in King Philip lodge of Mosons. In 1907 he was vice-president of the Bristol South District Medical Society and in 1908 its president.

A retiring man, he avoided public office. His ideals were high as regards the practice of his profession, carrying into the sick chamber the best ethical standards. A large circle will mourn his loss.

Correspondence.

ATTITUDE OF THE STATE TOWARD THE
DRUG ADDICT.

Mr. Editor:

I am requested by Dr. Kline to call your attention to editorial on page 751 "The Attitude of the State Toward the Drug Addict" in your journal of June 1, 1922, Vol. 186, No. 22. Enclosed you will find a copy of Chapter 535, Section 1 being marked. This chapter was approved June 13, 1922.

Very truly yours,

RANSOM A. GREENE.

Assistant to the Commissioner, Department of Mental Diseases.

[Chap. 555.]

AN ACT RELATIVE TO CERTAIN PENALTIES FOR THE VIOLATION OF CERTAIN LAWS RELATING TO NARCOTIC DRUGS AND TO COMMITMENTS OF DRUG ADDICTS AND DIPSO-MANIACS.

Be it enacted, etc., as follows:

SECTION 1. Chapter ninety-four of the General Laws is hereby amended by striking out section two hundred and nine and inserting in place thereof the following:—*Section 209.* No person, not being a physician, dentist, nurse or veterinarian registered under the laws of this commonwealth or of the state where he resides, or a registered embalmer, manufacturer or dealer in embalming supplies, wholesale druggist, manufacturing pharmacist, registered pharmacist, manufacturer of surgical instruments, official of any government having possession of the articles hereinafter mentioned by reason of his official duties, nurse acting under the direction of a physician, employee of an incorporated hospital acting under the direction of its superintendent or officer in immediate charge, or a carrier or messenger engaged in the transportation of such articles, shall have in his possession a hypodermic syringe, hypodermic needle, or any instrument adapted for the use of narcotic drugs by subcutaneous injection. No such syringe, needle or instrument shall be delivered or sold to, or exchanged with, any person except a registered pharmacist, physician, dentist, veterinarian, registered embalmer, manufacturer or dealer in embalming supplies, wholesale druggist, manufacturing pharmacist, nurse upon the written order of a physician, or an employee of an incorporated hospital upon the written order of its superintendent or officer in immediate charge. A record shall be kept by the person selling such syringe, needle or instrument, which shall give the date of the sale, the name and address of the purchaser and a description of the instrument. This record shall at all times be open to inspection by the department of public health, the boards of registration in medicine, veterinary medicine, and pharmacy and the board of dental examiners, authorized agents of said department and boards, and police authorities and police officers of towns. Whoever violates any provision of this section shall be punished by a fine of not more than one hundred dollars or by imprisonment in a jail or house of correction for not more than two years, or both.

SECTION 2. Section two hundred and ten of said chapter ninety-four is hereby amended by striking out, in the fifth and sixth lines, the words "a fine of not more than one hundred dollars or by imprisonment for not more than one year", and inserting in place thereof the words:—imprisonment for not less than three months nor more than two years,—so as to read as follows:—*Section 210.* Each building, place or tenement which is resorted to by habitual users of narcotic drugs for the purpose of using such drugs, or which is used for the illegal keeping or sale of the same, shall be deemed a common nuisance. Whoever keeps or maintains such a common nuisance shall be punished by imprisonment for not less than three months nor more than two years.

SECTION 3. Said chapter ninety-four is hereby further amended by striking out section two hundred and twelve and inserting in place thereof the following:—*Section 212.* Whoever has in his possession a narcotic drug with intent unlawfully to sell and deliver or to exchange such drug, or any part thereof, or whoever unlawfully sells, furnishes, gives, delivers or exchanges any narcotic drug in violation of any provision of sections one hundred and ninety-eight to two hundred and thirteen, inclusive, shall be punished by imprisonment in the state prison for not more than five years, or in a jail or house of correction for not less than one year nor more than two and one-half years.

SECTION 4. Section sixty-two of chapter one hundred and twenty-three of the General Laws is hereby amended by striking out, in the second and third lines,

the words "The Norfolk state hospital", and inserting in place thereof the words:—(the state farm, or to any other institution under the department of correction that may be designated by the governor,—so as to read as follows:—*Section 62.* Any of the judges named in section fifty, or a judge of the municipal court of the city of Boston, may commit to the state farm, or to any other institution under the department of correction that may be designated by the governor, to the McLean hospital, or to a private licensed institution, by an order of commitment, directed to the trustees, superintendent, or manager thereof, as the case may be made, in accordance with section fifty-one, accompanied by a certificate, in accordance with section fifty-three, by two physicians qualified as therein provided, any male or female person, who is subject to dipsomania or inebriety either in public or private, or who is so addicted to the intemperate use of narcotics or stimulants as to have lost the power of self-control. The judge receiving the application for such commitment shall examine on oath the applicant and all other witnesses, and shall reduce the application to writing and cause it to be subscribed and sworn to by the applicant. He shall cause a summons and copy of the application to be served upon such person in the manner provided by section twenty-five of chapter two hundred and seventy-six. Such person shall be entitled to a hearing unless after receiving said summons he shall in writing waive a hearing, in which case the judge may issue an order for his immediate commitment as aforesaid, without a hearing, if he is of opinion that the person is a proper subject for custody and treatment in the institution to which he is committed. The commitment may be made forthwith, if the examining physicians certify the case to be one of emergency. A person committed as aforesaid may be detained for two years after the date of his commitment, and no longer.

SECTION 5. Said chapter one hundred and twenty-three is hereby further amended by striking out section eighty and inserting in place thereof the following:—*Section 80.* The superintendent or manager of any institution to which commitments may be made under section sixty-two may, when requested by a physician, by a member of the board of health or a police officer of a town, by an agent of the institutions registration department of Boston, by a member of the state police, or by the wife, husband, guardian or, in the case of an unmarried person having no guardian, by the next of kin, receive and care for in such institution, as a patient for a period not exceeding fifteen days, any person needing immediate care and treatment because he has become so addicted to the intemperate use of narcotics or stimulants that he has lost the power of self-control. Such request for the admission of a patient shall be made in writing and filed at the institution at the time of his reception, or within twenty-four hours thereafter, together with a statement, in a form prescribed by the department having supervision of the institution, giving such information as it deems appropriate. The trustees, superintendent or manager of such institutions shall cause to be kept a local record, in such form as the department having supervision of the institution requires of each case treated therein, which shall at all times be open to the inspection of such department and its agents. Such record shall not be a public record, nor shall the same be received as evidence in any legal proceeding. The superintendent or manager of such an institution shall not detain any person received as above for more than fifteen days, unless, before the expiration of that period, such person has been committed under section sixty-two, or has signed a request to remain at said institution under section eighty-six.

SECTION 6. Section eighty-nine of said chapter one hundred and twenty-three is hereby amended by inserting after the word "hospital" in the third line the words:—or of any institution to which commitments may be made under section sixty-two,—by inserting

after the word "department" in the fourth line the words:—having supervision of the institution,—by striking out, in the seventh line, the words "supreme judicial" and inserting in place thereof the word:—superior,—and by inserting after the word "department" in the eighth line the words:—having supervision,—so as to read as follows:—*Section 89.* The superintendent or manager of a private institution described in section three, the superintendent of a state hospital and of the McLean hospital, or of any institution to which commitments may be made under section sixty-two, when authorized thereto by the trustees of such institution, the trustees themselves, the department having supervision of the institution, or, on written application, a judge of probate for the county where the institution is situated, or where the inmate had his residence at the time of his commitment or admission, or a justice of the superior court in any county, after such notice as the said superintendent, manager, trustees, department having supervision, judge or justice, may consider reasonable and proper, may discharge any inmate if it appears upon examination that he will be sufficiently provided for by himself, his guardian, relatives or friends, or that his detention in such institution is no longer necessary for his own welfare or the safety of the public. If the legal or natural guardian of any relative of an inmate opposes such discharge, it shall not be made without written notice having been given to the person opposing such discharge. This section shall not apply to persons committed by a court under any provision of sections one hundred to one hundred and five, inclusive.

SECTION 7. Chapter one hundred and twenty-three, as amended in section one hundred and thirteen by section one of chapter two hundred and seventy of the acts of nineteen hundred and twenty-one, is hereby further amended by striking out said section one hundred and thirteen and inserting in place thereof the following:—*Section 113.* At any time prior to the final disposition of a case in which the court might commit an offender to the state prison, the reformatory for women, any jail or house of correction, the Massachusetts reformatory, the state farm, the industrial school for boys, the industrial school for girls, the Lyman school, any county training school, or to the custody of the department of public welfare, for any offence not punishable by death or imprisonment for life, a district attorney, probation officer or officer of the department of correction, public welfare or mental diseases may file in court an application for the commitment of the defendant in such a case to a department for defective delinquents established under sections one hundred and seventeen and one hundred and twenty-four, or to a department for the care and treatment of drug addicts, established by the governor and council under authority of said sections. On the filing of such application the court may continue the original case from time to time to await disposition thereof. If, on a hearing thereon, it appears that the defendant, within a period of three years, has been found guilty of an offence for which he might have been committed to any institution above named or to the custody of the department of public welfare, or that he has been adjudged a juvenile delinquent, and that he is mentally defective, or addicted to the intemperate use of stimulants or narcotics, and is not a proper subject for the schools for the feeble-minded or for commitment as an insane person, the court may commit him to such department for defective delinquents, or to such a department for the care and treatment of drug addicts, as the case may be, according to his age and sex, as hereinafter provided.

SECTION 8. Said chapter one hundred and twenty-three is hereby further amended by striking out section one hundred and fourteen and inserting in place thereof the following:—*Section 114.* If an offender while under commitment to any of the institutions named in the preceding section or to the department of public welfare persistently violates the regulations

of the institution or department in whose custody he is, or conducts himself so indecently or immorally, or otherwise so grossly misbehaves as to render himself an unfit subject for retention in said institution or by said department, and it appears that such offender is mentally defective or addicted to the intemperate use of stimulants or narcotics, and is not a proper subject for a school for the feeble-minded, a physician in attendance at any institution named in the preceding section or a physician employed by said department shall make a report thereof to the officer in charge of said institution or to the director of child guardianship, who shall transmit the same to one of the judges mentioned in section fifty. The judge shall make inquiry into the facts and, if satisfied that the offender is mentally defective or so addicted, and not a proper subject for a school for the feeble-minded, shall order his removal to a department for defective delinquents or to a department for the care and treatment of drug addicts, as the case may be, according to his age and sex as hereinafter provided.

SECTION 9. Said chapter one hundred and twenty-three is hereby further amended by striking out section one hundred and fifteen and inserting in place thereof the following:—*Section 115.* No person shall be committed to a department for defective delinquents or to a department for the care and treatment of drug addicts under either of the two preceding sections unless there has been filed with the judge a certificate by two physicians qualified as provided in section fifty-three that such person is mentally defective or is addicted to the intemperate use of stimulants or narcotics. The fees of the certifying physician shall be of the amount and paid in the manner provided for like service in sections three to one hundred and twelve, inclusive.

SECTION 10. Said chapter one hundred and twenty-three, as amended in section one hundred and seventeen by section two of chapter two hundred and seventy of the acts of nineteen hundred and twenty-one, is hereby further amended by striking out said section one hundred and seventeen and inserting in place thereof the following:—*Section 117.* At the Massachusetts reformatory, the state farm or such other place or places as may hereafter be approved by the governor and council, there may be maintained departments to be termed departments for defective delinquents, for the custody of persons committed thereto under sections one hundred and thirteen to one hundred and sixteen, inclusive. At any state institution under the supervision of the department of correction, there may be established and maintained, with the approval of the governor and council, departments to be termed departments for drug addicts, for the care and treatment of persons addicted to the intemperate use of stimulants or narcotics and committed thereto under said sections. All men and boys so committed shall be committed to departments for male defective delinquents or for male drug addicts, as the case may be. All women and girls so committed shall be committed to departments for female defective delinquents or for female drug addicts, as the case may be. All such persons committed to departments for defective delinquents or for drug addicts at any institution under control of the department of correction shall be and remain in the custody of the said department until discharged as hereinafter provided.

SECTION 11. Section one hundred and eighteen of said chapter one hundred and twenty-three is hereby amended by inserting after the word "delinquents" in the second line the words:—or drug addicts,—so as to read as follows:—*Section 118.* The board of parole of the department of correction may parole inmates of the departments for defective delinquents or drug addicts on such conditions as it deems best, and may at any time during the parole period recall to the institution any inmate paroled.

SECTION 12. Section one hundred and nineteen of said chapter one hundred and twenty-three is hereby amended by inserting after the word "delinquents,"

in the second line the words:—or a department for drug addicts,—and by inserting after the word "delinquents," in the twenty-fourth line, the words:—or to a department for drug addicts, as the case may be,—so as to read as follows:—*Section 119.* Any person may apply at any time to the justice of the district court in whose jurisdiction a department for defective delinquents or a department for drug addicts is located, for the discharge of any inmate of said department. A hearing shall thereupon be held, of which notice shall be given to the applicant and to the person in charge of the institution where the inmate is confined. If after the hearing the justice shall find that it is probable that the inmate can be allowed to be at large without serious injury to himself, or damage or injury or annoyance to others, he may order the person having custody of said inmate to parole him. Further action on the application for the inmate's discharge shall be suspended for one year from the date of his parole. If, at any time prior to the expiration of said year, the justice of the court where the application was filed shall be satisfied that the best interests of said inmate, or of the public, require the recall of the inmate from parole, he may authorize the person having custody of the inmate to so recall him. If an application is denied, a new application shall not be made within one year after the date of the order denying the previous application. If at the end of said year the justice shall find that said inmate can be allowed to be permanently at large without serious injury to himself, or damage or injury or annoyance to others, he may order the person having custody of said inmate to discharge him. If a person discharged under this section is found by any court to have committed, after his discharge, any offence against the laws of the commonwealth, said court may commit such person to a department for defective delinquents or to a department for drug addicts, as the case may be, without the certificate of any physician.

Section 123. Section one hundred and twenty-four of said chapter one hundred and twenty-three is hereby amended by adding at the end thereof the words:—or for the care and treatment of drug addicts, as the case may be,—so as to read as follows:—*Section 124.* Sections one hundred and thirteen to one hundred and twenty-four, inclusive, shall take effect as to any of the departments named in section one hundred and seventeen when the same is ready for occupancy. The commissioner of correction shall notify the governor when a department is in a suitable condition to receive inmates; and the governor may then issue his proclamation establishing such department as a place for the custody of defective delinquents or for the care and treatment of drug addicts, as the case may be. [Approved June 13, 1922.]

LIABILITY INSURANCE.

August 9, 1922.

Mr. Editor:

A certain number of inquiries are made in regard to the liability insurance issued by the United States Fidelity and Guarantee Company of Baltimore to those members of the Massachusetts Medical Society who wish to insure under this policy. The policy is numbered PSD 8136 and is dated Nov. 10, 1921. The premium per member is \$21. The wording of the policy is as follows:

1. The Company does hereby agree to indemnify each Assured named in the representations hereof and herein called the Assured, against loss from the liability imposed by law upon the Assured for damages suffered by any person or persons in consequence of any malpractice, error, or mistake: (a) of the Assured in the practice of his profession during the term of this policy; (b) of any assistant of the Assured while assisting the Assured in the administration of

medical or surgical treatment during the said term:

2. The company agrees to defend in the name and on behalf of the Assured any suit brought against the Assured to enforce a claim, whether groundless or not, for damages on account of bodily injuries or death suffered or alleged to have been suffered, by any person or persons in consequence of any malpractice, error or mistake; (a) of the Assured in the practice of his profession during the term of this policy; (b) by any assistant of the Assured while assisting the Assured in the administration of medical or surgical treatment during the said term:

Subject to the following conditions:

Condition No. 1: The Company's liability for loss resulting from one claim or suit is limited to FIVE THOUSAND DOLLARS, and, subject to the same limit for each claim or suit, the Company's total liability under this policy is limited to FIFTEEN THOUSAND DOLLARS. The expenses incurred by the Company in defending any suit, including the interest on any verdict or judgment and any costs taxed against the Assured, will be paid by the Company in addition to the limits expressed above.

Condition No. 2: Any person shall be deemed to be assisting the Assured if such person is a physician, surgeon, dentist or nurse, and is temporarily acting as a substitute for the Assured in an emergency when the Assured cannot act, or during a period in which the Assured is not actively engaged in his professional duties, or if such person is actually assisting the Assured (but not necessarily in the Assured's presence), under the Assured's instructions in the administration, by the Assured, of medical or surgical treatment in a case attended by the Assured.

Condition No. 3. This policy does not cover loss from liability for, or any suit based on error, malpractice or mistake, (1) of the Assured while in any degree whatever under the influence of intoxicants, anaesthetics, or narcotics, (2) of the Assured or any assistant of the Assured in connection with the violation of any law or ordinance, but the Company shall not decline to defend any suit brought against the Assured for damages because such suit is based on an allegation of criminal malpractice; provided that the Company shall not be liable for or on account of, the recovery of damages in any suit.

Condition No. 4: In case the Assured receives notice of any malpractice, error or mistake covered hereunder, or any alleged malpractice, error or mistake, the Assured shall give immediate written notice thereof with the fullest information obtainable at the time to the Company at its Home Office in Baltimore, Maryland, or to the Boston Branch Office of the Company. If any claim is made against the Assured on account of any malpractice, error, or mistake covered hereunder or on account of any alleged malpractice, error or mistake, the Assured shall give like notice thereof with full particulars.

Condition No. 5: If thereafter any suit is brought against the Assured to enforce a claim, the Assured shall immediately forward to the Company at its Home Office or to the Boston Branch Office of the Company, every summons or other process as soon as the same shall have been served on him. The Assured shall at all times render to the Company all co-operation and assistance within his power.

Condition No. 6: No claim covered by this policy shall be settled or compromised by the Company without the consent of the individual member against whom claim is brought. If said member is in doubt as to the advisability of compromising such a claim brought against him he shall have that privilege of submitting the matter to a committee of members of this group, one to be selected by himself, one to be selected by the Company and three members to be selected by the group. The facts of the case shall be presented to this committee, whose decision is for

the guidance of the member against whom claim has been brought, it being understood and agreed that his right to make the final decision is not thereby surrendered or relinquished.

Condition No. 7: The defence of any suit under this policy by the Company will be continued until a final decision is rendered in the Assured's favor, or until the case has been appealed to the highest court to which an appeal can be taken or until the suit has been settled with the written consent of the Assured.

Condition No. 8: The Assured shall not voluntarily assume any liability; nor incur any expense without the written consent of the Company previously given; nor, except at his own cost, settle any claim; nor, excepting as provided in Condition 6, interfere in any negotiations or legal proceedings conducted by the Company on account of any claim.

Condition No. 9: If the Assured carries a policy of another insurer, valid and collectible, against a loss covered in this policy, the Assured shall not be entitled to recover from the Company a larger proportion of the entire loss than the proportion between the amount of this policy and the total amount of his valid and collectible policies.

Condition No. 10: The interest of an Assured under this policy shall not be assignable to any other person.

Condition No. 11: The termination of the membership of an Assured in the Massachusetts Medical Society shall immediately cancel this policy so far as it applies to such Assured and the Company will return on demand the unearned premium due on account of such cancellation. The failure of an Assured to pay, on or before the date when the same is due, any premium required to keep his policy in force shall on such date cancel this policy so far as it applies to the Assured.

The insurance of any individual Assured may be cancelled at any time by written notice given by the Company to such Assured, accompanied by check for pro rata unearned premium. Notice of cancellation may be given by the Trustee of the contract on behalf of all the Assured under this policy, in case of a majority of such Assured shall file with the Trustee of such group contract written notice instructing him to take such action and the Company's check for any unearned premium mailed to the Trustee shall be a sufficient tender.

A memorandum showing the date of any cancellation will be issued by the Company and mailed to the address of the Assured to whom it applies, and a duplicate of such memorandum shall be mailed to the Trustee of the contract. The date named in such memorandum shall be the date of cancellation of this policy so far as it applies to such Assured named therein.

Condition No. 12: No erasures or change appearing in this policy as originally printed, and no change or waiver of any of its terms or conditions or statements, whether made before or after the date of this policy, shall be valid unless set forth in an indorsement added hereto and signed by the President, the Vice President, or any one of the Secretaries of the Company. Notice given to or the knowledge of any agent or any other person, whether received or acquired before or after the date of this policy shall not be held to waive any of the terms or conditions of this policy or any of the representations in any application therefor. An Assured, by the acceptance of a certificate of insurance based on this policy, agrees that the terms and conditions of said policy embody all agreements then existing between himself and the Company or any of its agents relating to the insurance described herein.

Condition No. 13: The word Assured as used in Condition 1, 5, 6, 7, 8, and 9, shall be deemed to include the Assured's estate.

Condition No. 14: The date of this policy is November 10th, 1921, but the policy period as to each Assured named in the representations or amendments thereof shall commence on noon of the date set opposite the name of such Assured, and shall continue until the policy is cancelled as to such Assured in accordance with provisions of amended Condition No. 10 of this endorsement.

Condition No. 15: In consideration of the reduced rate at which this policy is issued, it is hereby understood and agreed between the members of the Massachusetts Medical Society insured hereunder and the Company, that, in event of any suit under this policy any of the said members insured shall give, when requested, testimony in court or advice on committee as provided in Condition No. 6 of this policy without demanding or receiving any charge or fee therefor from said Company. But this agreement shall not be construed to exclude the payment of any necessary expense incidental to such testimony, which may be incurred by any member.

The above conditions are all attached to and forming part of policy PSB-S126, issued by the United States Fidelity and Guaranty Co. to members of the Massachusetts Medical Society of Massachusetts, dated at Boston, Mass., this 10th day of November, 1921.

The above is countersigned by George H. Crosby, the authorized representative of the Company.

The representations which must be made are these:

(1) I am a member of good standing of the Massachusetts Medical Society and licensed to practice medicine in Massachusetts.

(2) I have not in force and I will not enter into any special written contract or agreement guaranteeing the result of any operation or treatment.

(3) Partner's or Assistant's Name.....

(4) I specialize in

(5) I was born....(day)....(mo.)....(yr.)....

The rates for policies in larger amounts are 5,000-15,000.....\$21; 10,000-30,000.....\$28; 15,000-30,000.....\$31.50.

The original of this policy I hold in my possession.

Yours very truly,

James S. Stone.

BARNSTABLE DISTRICT MEDICAL SOCIETY.

Mr. Editor:

Following is an account of the August meeting of the Barnstable District Medical Society, held at the Barnstable County Infirmary.

A splendid dinner, consisting largely of the products of the Infirmary farm was served under the able management of Mrs. Wagner. The meeting was called to order at two-thirty. Dr. Wagner gave an interesting address on the suppression of tuberculosis in Barnstable County, and the value of co-operation among the fellows. His talk was illustrated by a number of radiographs of cases which were viewed by everyone with great interest.

Dr. Frank Dunbar next addressed the meeting, choosing as his subject, "The Physician and The Laboratory." The need of such an address was clearly felt, and Dr. Dunbar did admirable justice to the subject.

During these speeches Mr. Mecarta, the milk inspector, entertained the ladies with a series of tests which are used to determine the purity of milk.

Dr. Russell B. Sprague closed the program with a talk on Public Health work. This final speech has certainly made for a better understanding of his work and its difficulties by the fellows.

The meeting was closed by a standing vote of thanks to Dr. and Mrs. Wagner for their most kind and hospitable treatment of the guests.

Paul P. Henson, M.D.,

Sec. Barnstable District Medical Society.

THE THERAPEUTIC USE OF BLUE LIGHT.

Mr. Editor:

I wish to call attention to the excellent little article by Dr. Romeo on the use of violet ray in the treatment of variola. While not original with him, it is an excellent addition to the proof we have of the value of the use of blue light in the treatment of certain skin lesions.

The point I wish to make is, however, as to the use of the term "violet ray." The doctor uses it correctly, although he might equally well use the term *blue light*. As used by him, it is the rays which we call blue that produce the effects so gratifying to the patients as recorded by him.

The criticism which I would make, and I would do so with all the emphasis possible, is the ridiculous and erroneous custom of calling the use of high frequency by means of a vacuum tube "violet rays." The color of the tube when in use is incidental and not fundamental, and depends upon the degree of vacuum to which the tube is exhausted. A low vacuum produces the violet color. Higher vacuum gives shades of red. And still higher, greens similar to the x-ray tubes.

The term should always be used as Dr. Romeo uses it, and not as a synonym for high frequency.

Very truly,

FRANK E. STOWELL, M.D.,
44 Pearl Street, Worcester, Mass.

PUBLIC HEALTH LECTURERS FOR THE YEAR 1922.

The Committee on Public Health of the Massachusetts Medical Society has been able during the past three years to arrange with well known specialists in various medical fields to give talks at meetings of the District Medical Societies on subjects of interest and importance to all practitioners. It is a pleasure to announce that a similar arrangement has been made this year and that the gentlemen named below are willing, without expense to the District Society, to give occasional talks of thirty to forty minutes on subjects relating to the promotion of public health, extending opportunity for questions and discussion. It is suggested that medical societies consider meeting at neighboring public institutions, since such meetings have been most successful in the past, particularly at the tuberculosis sanatoria and state hospitals for the insane.

José Penteado Bill, M.D., Doctor of Public Health, Specialty: Preventive Medicine.

Frank C. Dunbar, M.D., Bacteriologist, Instructor in Bacteriology and Pathology, Tufts College Medical School. "Methods of Technique in Collecting Specimens."

Walter E. Fernald, M.D., Superintendent, Massachusetts School for the Feeble-minded.

Timothy Leary, M.D., Professor of Pathology, Tufts College Medical School; Medical Examiner, Suffolk County.

Edwin H. Place, M.D., Physician-in-Chief, South Department, Boston City Hospital. Specialty: Contagious Diseases.

C. Morton Smith, M.D., Chief of Department of Syphilis, Massachusetts General Hospital.

George Gilbert Smith, M.D., Assistant in Department of Genito-Urinary Diseases, Massachusetts General Hospital. Specialty: Genito-Urinary Diseases.

Lesley H. Spooner, M.D., on Staff of Out-Patient Department, Massachusetts General Hospital, Specialty: Specific Diagnosis and Treatment of Pneumonia.

William C. Woodward, M.D., Ex-Health Commissioner, City of Boston.

George H. Wright, D.M.D., Lecturer on Dental Hygiene, Harvard Dental School. Specialty: Dental Surgery.

Thomas F. Kenney, M.D., Director of School Hygiene, City of Worcester. Specialty: Full time School Health Office.

Secretaries of District Medical Societies writing to ask for these lecturers will kindly designate the topic, the place and the hour of meeting as well as the name of the desired speaker, thus eliminating unnecessary correspondence. Please address communications to the Secretary of the Committee, Annie Lee Hamilton, M.D., 164 Longwood Ave., Boston 17.

[Note: The Committee on Public Health feels that this notice may have escaped attention, for few applications have been received. Each lecturer is an authority and would present his subject in an interesting and instructive manner.]

PAPERS AND DISCUSSIONS OF THE SECTION OF MEDICINE.

AT ITS MEETING AT THE HARVARD MEDICAL SCHOOL, BOSTON.

June 13, 1922.

CHRONIC SEPSIS IN PREGNANCY.

By JOHN E. TALBOT, M.D., WORCESTER.

THE problem of chronic sepsis as an etiological factor in the diseases of the human system is so large that it would be impossible to present it as a single clinical unit. There is in obstetrics, however, an opportunity to study its workings to better advantage because of a less diversified set of manifestations. It is the purpose of this paper to call attention to the presence of a large clinical entity in obstetrics which has chronic sepsis as its initial lesion.

Many cases in obstetrics manifest a persistence of pathology in each successive pregnancy. The woman who has repeated uninduced miscarriages, "the habit of abortion," as it is called, is a well recognized unit. Some cases, however, show a great variety of pathological events.

This persistence of pathology strongly indicates the presence of some continuous etiological factor in the case.

The problem, therefore, becomes one of finding a continuous etiological factor and working out the process by which this etiological factor produces its variety of manifestations.

No one disease entity plays so important a rôle in the pathology of obstetrics as toxemia of pregnancy with or without convulsions.

Early in 1917 I had two cases at about the same time which directed my attention to the association of chronic sepsis with toxemia of pregnancy and eclampsia.

Observations made during the subsequent year convinced me that chronic sepsis was always present in association with toxemia and eclampsia. After writing a paper¹ recording this feature and endeavoring to explain the relationship, I found that La Vake² of Minnesota had written a paper in 1916 to the same effect. Mosher of Kansas City³ has also called attention to the frequent association of chronic sepsis with toxemia of pregnancy. After five years of observation I am still convinced of the constant association of chronic sepsis with toxemia of pregnancy. Here, therefore, is a constant etiological factor of the type which would persist throughout subsequent pregnancies and fulfill the first requirement of the problem.

There are, however, other manifestations of pathology in obstetrics which sometimes occur without the association of toxemia, yet they have so much greater incidence in those cases that are toxic that they are believed to be a part of the clinical entity of toxemia. I refer to such

units as antepartum hemorrhage, abruptio placentae, macerated fetus, hydramnios and deformed babies, and premature babies. My own observations would add to this list miscarriages, inanition fever, and hemorrhagic disease of the new-born.

Can all these manifestations be so correlated as to explain their frequent association with each other and with or without the association of toxemia, and lastly with the hypothetical etiological factor chronic sepsis?

The most constant bit of pathology which is found in association with toxemia of pregnancy is the placental infarct. If this so-called "infarct" can be proved to be infectious in origin, the whole problem can be explained.

Young of Edinburgh¹ has shown that infarction can be caused by thrombosis of the maternal blood-vessels of the placental site.

La Vake of Minnesota² has pointed out that thrombosis in other parts of the body is accepted as infections in origin and further suggests that the chronic sepsis which is always found in association with eclampsia may be the source of the infection which results in the thrombosis of the maternal blood vessels of the placental site. His paper published in 1916 is the first so far as I know which places the cause of eclampsia squarely upon chronic sepsis.

Bacteriological methods to prove that the infarct is infectious in origin have not proved successful. De Lee³ isolated a staphylococcus from an infarct in a single case 20 years ago.

The clinical phase of this problem has not been studied before so far as I know.

The sequence between acute infection in the head and miscarriage and threatened miscarriage has occurred with very impressive frequency in my experience. In the last part of 1920 two cases showed evidence that the damage done by the bleeding in threatened miscarriage was recorded on the edge of the placenta in the form of a white infarct and that the position of these infarcts in relation to the base of the cord demonstrated that the infarct must have originated at the time the bleeding occurred. These two cases were reported in *Surg., Gyn. and Obst.*, under the title, "A Clinical Study of the Placenta."⁴

Since that time I have been able to acquire a considerable series of cases in which the position of the infarct on the placenta has been coincident with a bleeding spell and in many of them there has also been the clinical factor of an acute infection just preceding the bleeding spell. In some cases an acute cold was recorded on the placenta by an infarct contemporaneous in its position on the placenta but without evidence of bleeding. Using this sequence of events it has been possible in some cases to accurately foretell the shape of the placenta and the position of infarcts on the placenta before birth. This prophecy is subject to so many elements of negative error that it can not be advanced as

infallible. Positive results are, however, very convincing.

The frequency with which uterine bleeding in pregnancy is preceded by active infection in the head is only apparent when it is carefully searched for. The relation of cause and effect in this sequence is convincing when it is found that an acute infection is sometimes recorded on the placenta in the form of a white infarct so situated on the placenta as to show that it originated contemporaneously with the acute infection, although there may have been no evidence of external uterine bleeding. I do not wish to imply that every bleeding spell is preceded by demonstrable acute infection in the head nor is every acute infection recorded on the placenta. Bleeding spells unassociated with acute infection have, however, always been associated with chronic sepsis in my experience.

It must be borne in mind that the early infarct is hemorrhagic in nature and that the white infarct is the end-result of this hemorrhagic lesion.⁵

Clinically the uterine bleeding which is associated with the beginning infarct does not come from the hemorrhagic lesion in the placental tissue but from the uterine blood-vessels, since it is the mother who becomes exsanguinated in uterine hemorrhage.

Besides this clinical evidence there is laboratory evidence that the primary lesion which results in the placental infarct is in the maternal blood-vessels of the placental site and is infectious in origin.

A case reported by Cornell and Earle⁶ is extremely important on account of the unique set of circumstances which made the obtaining of the evidence possible. In this case a woman in her sixth pregnancy had a bleeding spell at the second month, immediately following a chronic cold of three weeks' duration. Examination revealed an asymmetrical uterus, and the abdomen was opened on the diagnosis of extra-uterine pregnancy. A bicornuate uterus was found with a pregnancy in one side and a fibroid in the other. A hysterectomy was decided upon and a complete pathological examination of the placenta and uterus was made with the placenta *in situ*.

It is hard to conceive of another set of surgical indications which would lead to a hysterectomy just following a bleeding spell in a pregnant uterus. The case, therefore, assumes a great importance on the question at issue. The pathological report describes "an abundance of necrotic areas in the decidua adjoining the intervillous space. They show profound necrosis centrally, there may be some hemorrhage and there is a margin densely infiltrated with leucocytes. Slides stained with Gram's stain afford some inconclusive evidence of the presence of Gram-positive cocci but the histological appearance of the necrotic areas points clearly to their infectious origin."

To summarize this case we have multiple direct hemorrhagic lesions of infectious origin in the decidua basalis and in association with a threatened miscarriage which in turn was immediately preceded by infection in the throat.

W. S. Thompson of Johns Hopkins⁹ has reported a case of hysterectomy on a case of complete placenta praevia. The pathological examination was made with the placenta *in situ* and the report contains the following extracts. "At the junction of the decidua with the chorionic membrane there are numerous areas of closely packed polymorphonuclear leukocytes in various stages of preservation which apparently represent minute miliary abscesses. Sections through the posterior wall of the placental site show that the placenta is almost entirely infarcted and presents numerous areas of calcification. Leucocytes extended far out into the muscularis, forming parallel rows between the fibers." This histological examination of the uterine tissues beneath this much infarcted placenta shows marked evidence of long standing infection.

It is my belief that the first case represents the picture of beginning infarction of the placenta; the second is the picture of the end-result.

The infectious origin of the infarct is again supported by the clinical observation that it is most frequently found in association with three diseases—toxemia of pregnancy, chronic nephritis, and syphilis. Toxemia of pregnancy is constantly associated with chronic sepsis; chronic nephritis is today recognized by many as being the result of chronic sepsis; and syphilis is the best understood of our chronic infectious diseases.

The analogy between the results of syphilis in pregnancy and chronic sepsis in pregnancy is most striking.

Before the Wassermann test was widely used, repeated miscarriages were considered to be a symptom of syphilis. Macerated fetus and deformed babies were also believed to be evidence of syphilis. No one doubts today that syphilis is the etiological factor in many cases of repeated miscarriages, of toxemia, of macerated and deformed babies and of premature births. Infection of the placental site by the spirochaete is known to produce a much damaged placenta and these bacteria often pass through the villous membrane and infect the fetus. Similarly pneumococci,¹⁰ influenza bacilli,¹¹ streptococci¹² and staphylococci¹³ have been found in stillborn and living babies. A case of miliary tuberculosis¹⁴ in a stillborn infant has recently been reported. All this evidence demonstrates plainly the principle of hematogenous infection of the placental site. I believe the situation may be summed up by the statement that everything that syphilis can do in pregnancy can be done by chronic sepsis of other types of bacteria.

The evidence tends to show that such units as threatened miscarriage, miscarriage, ante-

partum hemorrhage and abruptio placentae are all manifestations of the same process, differing only by reason of the site of the lesion, the degree of the damage and the virulence of the bacteria causing the lesion. Threatened miscarriage and antepartum hemorrhage from normally implanted placentas represent bleeding from the edge of the placental site. Miscarriages and complete detachment may result from this process but may also result from retro-placental hemorrhage without initial external hemorrhage.

Macerated fetus and deformed babies result either by direct infection of the fetus or by the interference with the oxygen supply of the fetus. Stockard of Cornell¹⁵ has produced twins, double monsters and deformities in fish by reducing the oxygen supply of the eggs at a crucial time in their development. In my series there are nine consecutive cases of deformed babies which were associated with evidence of placental damage at the base of the cord. The relationship of this damage to the base of the cord shows that the initial lesion occurred very early in the pregnancy.

Hemorrhagic disease of the newborn and inanition fever are evidences of infection of the fetus before birth by the presence of an acute infection of the placental site just previous to or during labor.

All these units depend upon infection of the placental site.

There is much evidence to show that toxemia of pregnancy is not the result of infarct formation or the result of infection of the placental site except that such infection may act as a new area of sepsis.

In a paper of this length it is not possible to discuss toxemia of pregnancy in detail viewed from the standpoint of chronic sepsis as the etiological factor. Let me mention in passing, however, that the multiple areas of necrosis in the liver of the dead elamptie suggest a strong analogy to the multiple necrotic areas found in the placental site of the much infarcted placenta. Emerson of Indianapolis¹⁶ has maintained that chronic nephritis is not a self progressive disease but the result of repeated minute acute infections of the kidney tissue. The analogy between this point of view and the rest of the picture as shown by the much infarcted placenta in association with chronic nephritis and toxemia of pregnancy is likewise most striking.

The degrees of toxemia of pregnancy may be explained by the kinds of bacteria involved in the areas of chronic sepsis and their virulence. This point of view makes it possible to explain why the results of infection of the placental site, such as antepartum hemorrhage, macerated and deformed babies, premature babies, hemorrhagic disease of the new-born and inanition fever are so frequently associated with toxemia

of pregnancy and yet may occur without evidence of toxemia.

The clinical sequence described in the beginning of this paper shows that the source of the sepsis is generally in the teeth or tonsils. Many of these tragedies of obstetrics are, therefore, preventable by the timely removal of these areas of chronic sepsis.

The removal of chronic sepsis in the presence of a pregnancy has, however, very definite limitations. There is a well known saying current among the medical and dental professions and among the laity that dentistry should not be done during pregnancy. I believe this saying is well founded when it is limited to the treatment of septic conditions in the teeth. It is well recognized that miscarriage is most frequent up to and including the third month of pregnancy. Up to that time the placental site is relatively small. A beginning infarct during this time would be more liable to terminate the function of a relatively large part of the placental area. If this damaged area is proportionately large enough it will asphyxiate the fetus by reducing the available oxygen supply and a miscarriage will result. It is, therefore, not safe to take a chance on increasing the activity of sepsis before the beginning of the fourth month.

It is likewise true that chronic sepsis should not be disturbed in the presence of toxemia of pregnancy. It is well recognized that many cases of toxemia are apparently precipitated by acute infection.

I heartily agree with La Vake,¹⁷ who believes that it should not be the duty of the obstetrician to remove chronic sepsis and that the proper time for its removal is either before or between pregnancies.

If chronic sepsis is found, however, in the pregnant woman, experience has shown that the safest time to have it removed is between the fourth and seventh month of her pregnancy.

CONCLUSIONS.

1.—The white placental infarct is the end-result of a hemorrhagic lesion, its evolution being described as a coagulation necrosis.

2.—The lesion is a discrete process, often multiple and often repeated in the same placenta.

3.—The placental lesion is secondary to a hemorrhagic lesion in the maternal blood vessels of the placental site.

4.—There is clinical and histological evidence that the primary lesion in the maternal blood-vessels of the placental site is infectious in origin.

5.—The clinical sequence of events observed shows that the lesion is the result of hematogenous infection and that the source of the infection is generally to be found in the teeth or tonsils.

6.—By the determination of the infectious origin of placental infarcts, a large clinical on-

lity is demonstrated in pregnancy which has chronic sepsis as its initial lesion.

7.—Treatment by the removal of areas of chronic sepsis in the presence of a pregnancy should be pursued with the greatest caution.

DISCUSSION OF DR. TALBOT'S PAPER.

DR. S. B. WOLBACH, Boston: There are a number of things in Dr. Talbot's paper that interest me. One is that one may time the occurrence of placental infarcts with something that has happened to the individual during the pregnancy. That seems very important because it gives the obstetrician or clinician an opportunity to test out one of the main points of Dr. Talbot's paper. I believe that it is probable that the growth of the placenta is only by peripheral extension. That has always been my conception, and I have conversed with embryologists in regard to this. When the fetal villi have implanted themselves they stay placed and new fetal villi extend peripherally during the growth of the placenta. An infarct at the extreme periphery of a fully developed placenta can occur only very late in the pregnancy. This can be tested out by anyone in charge of pregnant women.

I think Dr. Talbot should be congratulated upon having impressed that fact upon us.

The circulation in the placenta, of course, is extremely interesting, and the wonder is that accidents don't happen more frequently. Embryologists and physiologists have called attention to these large pools in which the blood bathes the fetal villi and the fact that the villi are not covered with endothelium but with epithelium. Of course, we don't know much about what goes on in the placental circulation, but theoretically it affords a good place for accidents, and from *a priori* reasoning, for the localization of infectious agents. From our work on animals we find that infection of the placenta occurs quite often. In working with organisms of low power of invasion we find that these organisms often invade the placental tissue, while other tissues are not invaded. I became interested in this some years ago, and know that it is possible to test out some of Dr. Talbot's work experimentally.

The only part of Dr. Talbot's paper I would deprecate in any way is the extent of his conclusions. I should think he must present much more evidence be-

fore he can prove that hemorrhagic disease of the new-born is due to infarction of the placenta. I deprecate that slightly, and also his use of the term "chronic sepsis." I should rather have him speak of coincident sepsis than of chronic sepsis, and leave the question of the importance of the tonsils and teeth in the same category where we place them in respect to some other diseases of infectious origin, such as chronic arthritis.

I want to impress upon you the strong impression that Dr. Talbot's paper has made not only upon myself but upon some other pathologists, and I sincerely hope that eventually we will learn more about the pathology of the placenta. If practitioners wish help from the pathologist in working out questions of this sort, the initiative must come from the practitioner; and it is desirable that he should do as much of the research as possible, aided by the pathologist.

DR. JAMES R. TORBERT, Boston: I have had the pleasure of discussing this subject with Dr. Talbot at prior meetings, and we are agreed. He is enthusiastic about his conclusions for he has done a great deal of work on the subject. He has taken a subject upon which, as you all know, the etiology is more or less in doubt and he has worked it up very well. I am basing my conclusions on the observations of a great many cases at the Lying-In Hospital here in town and also on a great many cases in private practice, and I can't believe that he has proven his point. For instance, we have seen in the last five years 6,000 cases at the Lying-In Hospital, with one case of eclampsia. We haven't found in that list any evidence to account for the fact that there is a focal infection in these cases. We have all the time in the hospital from five to six cases of toxemia of pregnancy, and since 1919, when this paper first came out, we have been looking for chronic sepsis constantly; and we don't always find it. Sometimes we do find it, and I cannot help but believe that there is something else at the bottom of this thing than chronic sepsis.

Now as to the question of infarcts in the placenta—we have been interested in that to a large extent, and we find a great many instances of infarcts which we can't explain at all. That is, there are no clinical data associated with these cases. Dr. Talbot has seen several of these cases with us and has admitted that he couldn't tell what had happened. I had a case last night in a patient who had a normal child and who had a normal pregnancy throughout, and yet who produced this malformation of the placenta in which we should be able to put our finger on the cause, but there was nothing to be seen in this case. The way I feel about the subject is that this may be one of the causes, but it has not been proven yet; and the fact we have so many cases that show no evidence of chronic sepsis proves the question to be one that is still open for discussion. I have no theory or facts to contradict this other than clinical observation, and I have no idea about the cause of eclampsia. Dr. Wolbach said that when we get up here we will have the assistance of the pathology department and chemistry department and thus we may be able to get a line on the cause, but I have followed Dr. Talbot's paper since 1919 and I am not convinced that there is enough in it to be the actual cause of the condition.

He mentions another subject which we discussed together and that is, the careful observation of these cases. Now, at the Lying-In Hospital it is very difficult to get a definite history of a slight hemorrhage which has occurred during pregnancy. That is perfectly true, we all agree; but on the other hand, where I had been able to get a definite history, I haven't been able to make the facts agree with the pathologist's findings which were present, and I think that there is something else besides this condition which he mentioned as a basis for the various combinations. I feel that my point is very weakly taken, but it is simply the result of observation on a large number of cases, and the only one I have come across where

there was definite evidence of chronic sepsis was one case of eclampsia where there was definite infection in the month. In the other cases we haven't x-rayed all the teeth, as Dr. Talbot suggests, but there was no clinical evidence of infection in the month at the time of the convulsive seizures or afterwards.

DR. FREDERICK C. IRVING, Boston: I am very much inclined to agree with Dr. Torbert on this question. I think Dr. Talbot has made an important contribution to the theory concerning the pre-eclamptic toxemia. In other words, I think his focal infection theory is worthy of taking its place amongst the other theories such as the nephritic theory, the numerous biochemical and serological theories which have been advanced, and the intestinal toxemia theory of the Dublin school. But I agree with Dr. Torbert that I don't think it is the whole story. And the reasons I don't think it is the whole story are these: In the first place, in order to demonstrate anything in medicine or in anything else you not only have to prove that a certain fact is true but you have to prove that the opposite cannot be true. In other words, you have to have controls. Now, if Dr. Talbot has been able to demonstrate that his cases that did not have toxemia or did not have deformed babies or placenta previa or miscarriage, did not have chronic sepsis, then I think we would be more ready to accept his theory. Also there is lacking the bacteriological proof. There is no bacteriological evidence to prove that the same micro-organism which caused sepsis caused any of these conditions. Moreover, as I understand it, in his opinion chronic sepsis is in some way involved in the following conditions: toxemia, placenta previa, separation of the normally implanted placenta, miscarriage, premature labor, deformed children, lumbago fever and hemorrhagic disease of the new-born. If that is so, it is a unique situation in medicine. Even syphilis, which has so many manifestations, has not so many as this. And it seems to me, to say the least, it is unlikely. Another thing which is hard for me to understand is why chronic sepsis should not be drained during pregnancy. Why, if it is the etiological factor, should it not be eliminated, that is, the sepsis treated under surgical principles? I believe in other conditions where chronic sepsis is believed to be the causative factor, drainage is indicated. At the pregnancy clinic at the Lying-In Hospital we have a class of patients who are not particularly careful about dental hygiene. Their teeth are in an unbelievably bad condition. There must be a great deal of chronic sepsis among them, and yet we find in a series of 5,000 consecutive cases that toxemia occurred in only one and a half per cent. It seems to me if chronic sepsis and sepsis of the teeth are so important, that we would have found toxemia much more commonly than we have.

DR. F. S. DELUE, Boston: I believe that there is another factor here other than chronic sepsis. I firmly believe that the process is a nutritional one and that that which causes the focal infection causes the hemorrhage. The condition of the body which robs it of its supply of lime and various other alkalies which neutralize the acids is the condition which gives rise to hemorrhage, whether it be in the eye, skin or placenta or elsewhere. I have found invariably that those cases were cases of primary acidosis, cases in which the lime was evidently deficient in one part of the body or another. Ten years ago I showed Dr. Wolbach a peridental abscess which I told him I could produce at will. In these infections there may be hemorrhage around the teeth, into the anterior chamber, or into the skin, and these are entirely due to improper eating, eating acid fruit being one cause. You have been taught that fruits render the body fluids alkaline whereas it is just the reverse. In using the hydrogen ion concentration test you find that fruits are distinctly acid. When you are constantly using up your lime supply and piling in acid

you get your hemorrhages, due to the alkaline supply being disturbed. We find this condition where there are no teeth and no infected tonsils to act as the focus of infection. The process is an aseptic one; if there are germs present they are secondary and not primary. If you have a rotten tooth or an infected tonsil, take it out; but that isn't the cause of the trouble. That which causes the acidosis causes the hemorrhage, in my opinion.

DR. CRAW: I have a patient who is six months pregnant, about 26 years of age, first pregnancy. X-ray has shown that she has two teeth in the lower jaw which have not erupted, and she has some pus from those teeth. Would you advise having those teeth extracted?

DR. JOHN E. TALBOT, Worcester: I do, as a matter of prevention.

DR. JOHN E. TALBOT, Worcester (closing): It is impossible to take up all the details in the time allowed. One thing is sure. I cannot share Dr. Torbert's views. He shows that he has a mistaken point of view of what I was trying to show. I do not claim that I can explain everything that shows in the placenta. The injury to the edge of the placenta is the type of injury which I am talking about, an infarct on the edge of the placenta. I think if you confine your study to that point, you will see that there is a great difference in the findings. I cannot take a placenta and look at it and tell all that has happened in the past history or whether there was clinical evidence of the damage. Chronic sepsis often works silently, without demonstrable clinical signs. The truth is shown by the demonstrable acute infections and the damage to the placenta contemporaneous with that acute infection.

With regard to the pathological study of the placental damage it seems to me the truth of the situation is to be found in the examination of the placenta *in situ*. The infection is in the uterine blood-vessels, not in the placenta. The infection does not necessarily cross the villous membrane. The infarct is an aseptic lesion as compared to the septic lesion which is in the maternal blood-vessels.

EPILEPSY.

By D. A. THOM, M.D., Boston.

To discuss the subject assigned me by the secretary of your section, in the time allotted, necessitates a selection of certain aspects of the problem which are of particular importance, and a consideration of them in their relation to the subject in its entirety.

No longer do we look upon convulsions, loss of consciousness, and changes in personality, as a disease entity, but rather as a syndrome of some underlying pathological condition.

The old conception of epilepsy and the search for some definite pathogenic factor with a no less definite anatomical location accounts to a great degree for our present-day ignorance regarding the etiological factors producing convulsions and therapeutic measures with which to combat them.

The syndrome which goes to make up the condition which has borne the name of epilepsy is neither constant nor characteristic. The signs and symptoms may be as numerous and as varied as it is possible for any organic lesion or psychogenic mechanism to produce which needs no definite pathology, no particular anatomical

site, no specific toxin or pathogenic organism. The convulsions caused by a lesion of the kidney are quite indistinguishable from those produced by an acute infection. In neither case may they differ from idiopathic epilepsy.

Notwithstanding the fact that it is highly desirable from a scientific point of view and for the good of the patient to look upon the convulsive disorders in this way and to utilize all our clinical and laboratory facilities in an effort to determine the underlying cause, all too frequently we are confronted with a residual which defies this method of scientific approach, and it is this group that we may quite properly term idiopathic epilepsy.

Before we are justified in making a diagnosis of epilepsy, it is necessary at the outset to eliminate the following organic conditions which are accompanied more or less frequently by convulsions.

Convulsions due to Gross Brain Lesions.

- | | |
|-----------------|--------------------------------|
| 1. Paresis | 2. Cerebro-spinal syphilis |
| 3. Brain cysts | 4. Hydrocephalus |
| 5. Meningitis | 6. Trauma |
| Tubercular | |
| Syphilitic | |
| 7. Encephalitis | 8. Arteriosclerosis (cerebral) |

Convulsions of Toxic Origin.

- A. Endogenous—Uremia, Diabetes, Auto Intoxication.
 B. Exogenous—Lead, arsenic, alcohol, strychnine.
 C. Infectious—1. By toxemia. 2. By producing a meningitis.

Conditions other than those mentioned.

Disturbances of the Internal Secretions.
 Disturbances of the Cardio Vascular System.

After the foregoing conditions have been excluded, of which either loss of consciousness or convulsions might be a symptom, such as a brain tumor, uremia or a syphilitic meningitis, we are still confronted with perhaps our most difficult task by a group of borderland cases, which seem to lie in that portion of the diagnostic field called No Man's Land. I refer to the convulsions observed so frequently in association with hysteria, and will review the diagnostic points in another part of the paper. Imagine, for a moment, this step has already been carried out and we are left with the residual which represents what we please to term essential or idiopathic epilepsy.

My conception of idiopathic epilepsy necessitates the presumption of an inherent, unstable nervous system, or perhaps it would be best understood if stated in terms of deficiency in the nerve cells and its processes and its inability to resist reacting to stimuli of such quality and quantity that would not ordinarily affect a normal nervous system.

Such a nervous system is able to cope with a *limited amount* of mental stress and strain quite efficiently. Many such individuals are combating successfully the every-day problems of life. It is only when the potential epileptic is confronted by circumstances and conditions which require mental stamina or physical endurance in excess of this average, that he finds that his limited reserve has been completely utilized and there is no further resistance to stimuli, regardless of their origin.

The war was an especially good example of a situation which was continually and repeatedly demanding a degree of stability of the nervous system far greater than most conceivable situations, so that many individuals who broke down under such unusual strain, might well have stood the strife of civil life unimpaired. There appears to be a limit to the amount of physical strain and mental stress that every individual is capable of bearing, determined not only by the inherent qualities of the individual, but also by the environmental conditions during the formative period of early life.

Some of the theories that have been advanced to account for the convulsive phenomena in idiopathic epilepsy are perhaps worthy of mention. Of the older views and those subscribed to by many authorities of the time, that of *vasomotor spasm* which Tenor and Kusnau sponsored, was perhaps the most popular, as well as the most plausible, the site of the lesion being the vasomotor center in the medulla. Sclerosis of the cornu ammonis and lesions of the sympathetic ganglia described by Merynert and Echebrija respectively, both had many adherents in their day. Of the more recent theories which have been presented for our consideration, one which considered the increased rapidity of the coagulation time of the blood as responsible for convulsive disorders, was brought forth in 1912 by Sprangler of Philadelphia who recommended the injection of snake venom as treatment.

Another theory which attributed epilepsy to an infection due to the specific organism called the bacillus epilepticus described by Charles Reed of Cincinnati, ex-President of the American Medical Association, received considerable attention about 1915. The psychogenic theory expounded by Dr. L. Pierce Clark of New York has been gaining many adherents during the past eight years. Clark states that "epilepsy is a psycho-biological reaction and is double motivated. First, it seeks to make away with an intolerable adjustment demand; second, to retreat, to regress where a state of harmony and peace are wont to prevail," referring to the primitive pleasurable state of intrauterine existence.

Dr. Walter E. Dandy of the Johns Hopkins Hospital, presented two cases early in 1920 of epilepsy that had apparently been cured by a new form of operative treatment, and concluded that epilepsy was due to a definite lesion of the

brain stating, "Am encouraged to a hopeful outlook for its treatment." The diagnosis of Jacksonian Epilepsy was made in the first case which was that of a man thirty-four years of age who had definite localizing symptoms. The second case was a boy eight years of age, also suffering from "focal epilepsy." It is obvious that the two cases presented by Dr. Dandy would not have been included in my conception of epilepsy, but inasmuch as his work attracted considerable attention, it seemed worthy of mention.

Dr. John Mason Little recently published in the BOSTON MEDICAL & SURGICAL JOURNAL, January 19, 1922, a most interesting article entitled "Observations on the Operative Treatment of Epilepsy" with a report of fourteen cases. Dr. Little had no "operative deaths" and felt that no harm was done to any of these patients. He states, "Without exception, there was temporary improvement. There were three cases which can be called cures, over eleven and a half years; eleven years, and five months; and ten years. Three are relieved and living useful and happy lives, nine, six, and five years after operation. My general impressions are," says Dr. Little, "that it has been well worth while." He wisely and cautiously sounds a note of warning against overenthusiastic surgery and indiscriminate operating for epilepsy, yet leaves us with but little doubt that there are certain cases that may be benefited by operative procedure, but they should be selected very carefully after intensive study on each case.

Perhaps the most recent experimental work that has been carried on relative to convulsive disorders, is that which has been stimulated by Dr. H. Rawley Geyelin of New York, relative to the acid secretion during prolonged fasting in epileptics. This is the only report available up to this time. Eleven patients, ranging from eleven to thirty-five years of age, were fasted for periods from fifteen to twenty-one days. The fast was employed as a method of treatment on this group and careful examinations were made to determine quantitatively the following substances in the urine; creatinin, creatin, ammonia acid, titrable acid, total acetone bodies and total nitrogen. Quoting from Dr. Geyelin's paper, "There are five cases which show a relative high excretion of total N/10 acid. These cases also show a high total acetone excretion. The remaining seven cases show a relative lower acetone excretion." The therapeutic results observed seem to be somewhat dependent upon the total amount of acid excreted; that is, in general those patients who showed the highest acid excretion, were those who derived the maximum relief of symptoms. All those patients who showed the lower total acid excretion were not improved symptomatically except during the period of fast.

Dr. Stanley Cobb of the Harvard Medical School has devoted much time to experimental

work and clinical observations on the effects of fasting on convulsions, and will be able to give you a much more intelligent account of what may be expected of this method of treating epilepsy than I. I would say, however, that from the evidence presented, and the time that has elapsed since this experimental work began, we have no more reason to expect this line of treatment to be a panacea for all convulsive disorders, than other measures suggested heretofore, so that up to the present time none of the theories which have been advanced to which scientific research could be applied, have stood the test; either the results described were not sufficiently constant to be conclusive or the same lesions have been found to exist with some other clinical entity.

It is perhaps because so many of these idiopathic cases have their origin in childhood or early adolescence that the question of heredity has received, what I consider, undue importance and has had a tendency to lend an air of pessimism and hopelessness in the treatment of these cases.

In a study begun at the Monson State Hospital in 1916, and completed and read at the American Association of Psychiatry just a year ago this time, I was able to substantiate certain preconceived ideas regarding the transmissibility of epilepsy from parent to offspring.

One hundred seventeen cases were selected where the diagnosis of idiopathic epilepsy had been determined. Each case had been married and was a parent of one or more children. The total number of children resulting from these one hundred seventeen matings was four hundred thirty-one, of which two hundred eighty were still living at the time the study was finished, May, 1921. One hundred fifty-one were dead. To summarize briefly, nineteen of the one hundred fifty-one died of convulsions. Of the living cases, fourteen have had convulsions at some time during their life, but six have had remissions for a period varying between four and twenty-four years. The remaining eight of these offspring are still having convulsions and considered epileptic. Of the entire group, 75% of them were over twenty years of age, the zone where 70% of all convulsions begin.

The conclusions drawn from that study were as follows:

1.—Epilepsy as a disease is not transmitted directly from parent to offspring, but we believe rather that it is the nervous system, lacking in the normal stability, that is inherited, and the manifestations of this instability may be mental deficiency of varying degrees, mental diseases of different types, neurological and psychopathic disorders, and convulsions from various exciting causes, which would have little or no effect on a normally developed nervous system.

2. These mental and nervous disorders are less frequently found in the offspring of the

so-called epileptic than we have heretofore believed and the future of the offspring born of epileptic parents is not as hopeless as the pessimistic authorities on heredity have heretofore stated.

3.—Maternal defects are more frequently manifested in some form or other in the offspring than are the paternal defects and, when present, are more likely to appear at an earlier age.

4.—It was found that in only a few cases were we dealing with "pure cultures of epilepsy." In most instances contamination was brought about by some defect in the other partner such as feeble-mindedness, insanity, alcohol and syphilis.

5.—In this study it was determined that convulsive disorders were more frequently met with in the offspring of the organic group as compared with the idiopathic group. The organic group was, however, so small that too much consideration can not be given to this point. It should, nevertheless, stimulate further inquiry relative to the offspring of normal individuals and a larger group of organic cases.

6.—This study indicates the necessity of research relative to the transmissibility of genetic defects in both epilepsy and psychiatry. We feel that the dogmatism regarding this aspect of mental diseases has not been justified.

Another important problem relative to the convulsive disorders is the relation between convulsions in infancy and early life and the chronic convulsive disorders of adult life. This problem is worthy of far more consideration than it has received up to the present time.

Our attention is constantly attracted to the cases of epilepsy where the history indicates the first convulsion began during some gastrointestinal disturbance, teething, or at the onset of some acute infection, but with the exception of study made by Dr. John Lovett Morse and reported at the thirty-first annual meeting of the American Pediatric Society, no further researches or studies have been made to determine if any relation exists between the symptomatic convulsions in general and the chronic convulsive disorders in adult life.

Dr. Morse's aim was to determine what proportion of the children, having convulsions, but otherwise perfectly normal, had epilepsy, or developed it later, and to find out if there was anything in the history or the manner of the development of the convulsions to show whether or not there were manifestations of epilepsy, or whether they would be followed by epilepsy later. It appears, from his study, based on one hundred and seven cases, altogether too small a number on which to base any conclusions, that the convulsions associated with spasmophilia are likely to cease. One case out of ten became feeble-minded. One of the three cases where the infantile convulsions were associated with whooping cough developed epilepsy. Of thirty-

nine cases in which there was a single convulsion at the onset of some acute disease, two became epileptic and feeble-minded, a third had petit mal attacks and a fourth it is stated might or might not be epileptic. Dr. Morse concluded that it was impossible to determine from the nature of the earlier attacks, what to expect in the way of prognosis and he further stated that epilepsy is more likely to occur when the cause of the attacks is apparently an injury or severe labor than when the apparent cause is disturbance in the digestive tract. The longer the attacks have persisted, the more probable is the diagnosis of epilepsy. The prognosis in infantile convulsions must always be guarded, in fact, there is no way of telling what the subsequent history is going to be.

Another effort is now being made at the Massachusetts General Hospital to add further light on this subject and it may be possible to draw some conclusions which will be of assistance in making a prognosis as to the future in those cases suffering from infantile convulsions.

The evidence at hand all indicates that nothing should be left undone to determine the underlying cause of infantile convulsions and we already have reason to hope that the more modern methods of studying the biochemical reactions of the body will do much toward the solution of this problem. Clinical experience teaches us that in children, otherwise normal mentally and physically, convulsions persisting over any period of time are quite likely to prevent normal mental development, and that many of our infantile monoplegias, hemiplegias, and paraplegias are the result of convulsions and not a symptom of the same underlying process.

Although we do not understand we recognize that the convulsive habit must be taken into consideration and that heroic methods are justifiable in our effort to prevent the development of a motor pathway which may be too easily stimulated into activity.

Another aspect of this perplexing problem of the convulsive disorders is that of differential diagnosis between the functional and the organic cases and the possibility that the two conditions may exist in the same individual. I am forced to admit that, personally, more confusion exists in my own mind regarding the underlying mechanism, as to whether it be physiological or psychological in this group of cases, than in any other field of neurology.

Notwithstanding the clear, clean-cut differential diagnostic points as pictured in most textbooks, there are still many confusing cases which defy our present-day conceptions of either epilepsy or hysteria. The following illustrates this point.

Mrs. C., born in Connecticut, twenty-five years of age, birth and development normal. As a child she was considered unusually bright. When ten years of age she had her first convulsion, and attended the clinic at the Children's

Hospital. They were occurring infrequently, once in two or three months, did not prevent her from continuing her education to the second year in high school, when she left on account of an attack of rheumatic fever. The attacks usually occur at night, but since her marriage three years ago, she has had attacks at infrequent intervals during the day. These attacks are usually precipitated by heated arguments with her husband. There is apparently no aura, consciousness is lost completely, she bites her tongue, but does not wet or soil her clothing. Spells last about ten minutes and, from the description, have none of the dramatic characteristics associated with hysterical attacks.

The home situation was very chaotic when patient first came to the hospital, as the patient's father had accused her husband of endeavoring to have her put away in an institution on account of the frequency of her convulsions. Patient's mother-in-law had her child and she was not permitted to see it, and the patient was living with her own mother and her husband was living at his home. In spite of this estrangement, there seemed to be a desire on the part of both husband and wife for reconciliation and the case was turned over to the Social Service. The family difficulties were ironed out and the patient and her husband and child separated from the other members of the family and started to build up a little home of their own. This was in October, 1921. Patient was seen last May 17th. At that time she had not had a convulsion and things at home were going much more satisfactorily. The point of interest in this case is the fact that this woman having convulsions, beginning at the age of ten, which were epileptic in character, should at the age of twenty-two begin having attacks precipitated by emotional situations which, from an etiological point of view, would have been diagnosed as hysteria, but from the character of the convulsion itself, must be diagnosed as epilepsy.

There seems to be little doubt that convulsions of a psychogenic origin with all the characteristic features of hysteria may occur in an individual suffering from idiopathic epilepsy and I have one case in mind of an ex-soldier who had convulsions following head trauma, who has had three convulsions precipitated by emotional stress. These convulsions, however, were quite the same as our conception of the epileptic phenomena.

I appreciate fully how sketchy this presentation has been but I do not hope to do more than to put forward for the discussion of the meeting some of the present-day views concerning this most baffling condition. The more fundamental problems for consideration, I believe, are as follows:—First, the present-day conceptions of the pathology of the disease syndrome or symptom; second, the importance of hereditary factors; third, the futility of trying to crowd all convulsive disorders under one pathological en-

tity and advocating one specific treatment as a panacea for the condition. These are only a few of the important problems that demand intensive study before we can hope to clear away the present-day confusion concerning convulsions of either organic or functional origin.

DISCUSSION OF DR. THOM'S PAPER.

DR. STANLEY COBB, Boston: Dr. Thom has said that I was interested in the treatment of epilepsy and especially in the starvation treatment. The most useful thing that we have learned since 1915 is the use of luminal. Luminal has been of benefit to many patients and in some cases has made their lives practically free from convulsions. We must look upon treatment by luminal as symptomatic. In other words, we merely substitute it for bromides. You may use luminal over long periods without getting outward effects as in bromide poisoning. On the other hand, you are more likely in the unstable patient to have psychotic upsets from the use of luminal. Also it is unsafe to use in more than one and one-half grain doses, which should not be repeated more than once in 24 hours. In other words, any patient in whom you have to use more than three grains of luminal in a single day is a patient I would be afraid of, because later if you want to stop the drug, you might have a psychotic upset.

The second recent advance is the starvation treatment started by Conklin, an osteopath, some ten years ago. The fast is carried out for from ten to thirty days; the convulsions have ceased during the course of the fast in almost every case. The results of these fasts have in a small percentage of cases been remarkable; some have had no convulsions for months and years. Now that is an interesting result—not that you can use the treatment for all epileptics, but that it will stop the convulsions on some. The work has been followed up, as Dr. Thom said, by Dr. Geyen at the Presbyterian Hospital in New York, and he has had some satisfactory results; but on the other hand, there have been many cases that have not been substantially benefited. We know that we may stop the convulsions of some epileptics by starvation; if we could learn which cases would be benefited, it would be a useful method. We have so far been unable to learn any criteria by which to pick out those cases.

As to the pathology of epilepsy: Dr. Thom said that if we ruled out brain tumor, syphilis, the trauma cases, the meningitis cases and so forth, we had left a group of cases which we can speak of as "essential epilepsy," and that there were both psychological and organic precipitating factors. These arbitrary classifications are bad. As Dr. Thom said, the one underlying factor is an unstable nervous system, but I see no reason why we should not have that unstable nervous system from syphilis, maldevelopment, old meningitis, encephalitis or polio. As I see more autopsies, I find more organic pathology—an old encephalitis, an old scar or an aphasia. The apasias show an abnormal placing of the nerve cells or a lack of association fibers, probably inherited; but the amount of old encephalitis or meningitis is larger than I had suspected. As we improve our methods of examination, and if we can obtain autopsies on the early cases, not on the old chronic institutional cases, but the so-called idiopathic sort not having frequent convulsions, I think in these we may find evidence of great importance in relation to what may make the nervous system unstable and allow the factors such as alcohol, local infection, phlebotomy, or intestinal upset, to precipitate the convulsions. So when you stop the convulsions in an individual by circumcision or by extracting some bad molars or by a nasal operation, we should look upon the treatment as directed to remove the "last straw" from the patient's back and not as removing the cause of the convulsions.

DR. F. S. DE LEE, Boston: Dr. Thom has said that an unstable nervous system is usually at the foundation of these things. I think that is very true. I don't know of anything that will upset the nervous system as much as the ordinary eyestrain, and yet that isn't the whole story. Dr. Gould some years ago in trying this out went through an epilepsy hospital testing all the eyes and got very few results. Eyestrain is only one element. There is a reflex element here, and I think in those cases in which the eye is at fault we have to do with a reflex gastric hyperacidity which in its turn by irritating the pneumogastric causes the convulsion. I had an interesting case on my farm of a Hollander who had his warning and immediately went into a convulsion if he didn't go into the house for a dose of soda or a glass of milk to neutralize the acid. That may seem strange to many of you. Fifteen years ago I took the son of a Boston lawyer who was having seven convulsions a day when coming under my care at the age of seven years. These started at the age of eleven months. I put him on a diet of skimmed milk and bread without butter. During the winter he gained 9 pounds and his convulsions stopped. He had been operated upon and his skull trephined twice with no relief. I have seen three cases start from eating candy, without a doubt. I usually start my cases by fully correcting all errors of refraction and then attending to the diet.

The boy of seven, above referred to, while being given a bath one night suddenly began to scream. The nurse noticed that he did not have his glasses on and not seeing any other reason for his screaming, placed the glasses before his eyes, whereupon he immediately stopped screaming.

This boy had three dioptres of hypermetropia, which I immediately fully corrected. When first brought to me only one-half of the hypermetropia had been corrected.

I was interested in hearing Dr. Thom say that 13 years ago fasting was first suggested by an osteopath. I never have mentioned the name of the old army surgeon, Dr. Dewey, though over thirty years ago he advocated fasting for almost every disease under the sun.

DR. DOUGLAS A. THOM, Boston (closing): It is quite easy to find organic lesions of the same type in nearly every case of epilepsy. The question is what is the relation between the lesion and symptoms presented. A few years ago at the Monson Hospital we went over 256 autopsied cases, and it was interesting to note that in the high frequency group, those who were having the most convulsions, we found the more normal-looking brains, and in the group of cases that had fewer convulsions we found the abnormal-looking brains.

I don't think it is time to throw away bromides. Many patients stand bromides better than luminal, and in many cases sodium luminal can be combined with bromide, to great advantage.

THE PHYSICIAN AND THE LABORATORY.

By FRANCIS W. PEABODY, M. D., BOSTON.

THE important part which the laboratory has come to play in medical science is generally accepted and appreciated, but the relation which it should bear to clinical practice remains to be satisfactorily defined. It is obvious to all clinicians of experience that the laboratory never can become and never should become the predominating factor in the practice of medicine, but it is equally evident that sound medicine cannot be carried on without the support of the laboratory and that in the future the dependence of the clinic on the laboratory will prob-

ably increase rather than decrease. Among the men engaged in active medical practice, however, only a small minority can ever hope to undertake extensive laboratory work in connection with their patients, and the great majority of physicians are and will continue to be confronted by the difficult problem of their relation to this growing influence in medicine. To the teacher of medicine, whose foremost duty is to prepare his students for the practice of the future, the same problem presents itself, for the students must be thoroughly trained in the laboratory methods that will be of practical service, but not burdened with those that are highly specialized or of questionable value.

The leading exponents of clinical laboratory work are the large hospitals—especially the hospitals associated with teaching institutions—and these exert a profound effect on private medical practice, but the conditions existing in them are such as to demand for them a separate consideration. In such hospitals laboratory investigations fall into one of three categories. The first includes those which belong to the field of pure research, their object being to advance the limits of our knowledge of disease. With this we have, at present, no concern. The second consists of those laboratory methods that are applied in order to obtain direct aid in the diagnosis or treatment of individual cases of disease. This often means the use of standard methods of proved and known value—methods which have received general professional acceptance—but in addition it means the use of many methods of possible value, the significance of which needs to be thoroughly tested under conditions favorable for critical control. The trying out of newly advocated measures for the diagnosis and treatment of disease must always be an important function of the larger and better equipped hospitals. Many—indeed the majority—of such methods are found to be unreliable or of little practical value, and after their status becomes established they are discarded. Very rarely a new method withstands the test of prolonged observation and proves to be of such practical significance that it can be properly advocated for general adoption. This type of hospital thus serves as the court before which all such new ideas must stand trial and it is astonishing, if not depressing, to compare the enormous amount of time and labor that is spent in gathering evidence with the comparatively meagre results that pass the tests. The burden added to the hospital laboratories by such work is very great, but the importance of the function cannot be overestimated, for it filters out what is useful and protects the profession from much that is worthless.

The third category under which hospital laboratory work is carried on depends on the fact that every hospital is or should be an educational institution, and one of its primary duties is the instruction of all the members of the

staff in the nature of disease. Many of the laboratory data, therefore, that fill the pages of carefully compiled hospital records, do not have a direct diagnostic or therapeutic bearing on the individual case, but they contribute information which throws light on the pathological physiology and clarifies the disease process. In so far as the accumulation of such accessory laboratory observations is instructive to those who are studying the patients, the work is more than justified, but if, as sometimes happens, particularly with the younger members of the staff, it leads to the idea that all these observations are necessary for the proper diagnosis and treatment of any given case, the result may be most unfortunate. Properly used, such laboratory observations are enlightening and broadening; improperly used, they are blinding and narrowing. The real reason for taking an electrocardiogram on every patient with a cardiac arrhythmia is so that after one has studied the records of a large series of cases, he may understand the clinical manifestations of cardiac irregularities so well that he is able to recognize the type of arrhythmia without the electrocardiogram. His increased knowledge should, on the one hand, emancipate him from the need of the complicated apparatus in most cases, and, on the other hand, help him to appreciate the occasional case in which careful instrumental study is desirable. From this point of view, therefore, much hospital laboratory work may be regarded as of indirect significance for the individual patient, but aimed at the training of better clinicians. When, as sometimes happens, it results in the production of poor clinicians, unable to interpret disease except through the eyes of the laboratory, its purpose has failed and failed seriously.

The physician engaged in the actual practice of medicine is directly concerned, therefore, with only a small part of the laboratory work which is carried on in the larger hospitals, for his attention must necessarily be focussed entirely on those methods which contribute immediately to the better care of his patients. The methods of the teaching clinic cannot and should not be carried into extramural practice. In the hospital all manner of tests can readily be performed in obscure or doubtful cases, but in private practice the economic factor usually restricts one to the tests which most obviously offer practical assistance. Fortunately, however,—and this is apparently contrary to much present-day opinion,—good medicine does not consist in the indiscriminate application of laboratory examinations to a patient, but rather in having so clear a comprehension of the probabilities and possibilities of a case as to know what tests may be expected to give information of value. Even so-called thoroughness should be tempered by reason, and the reason that must dictate the part which laboratory tests shall play in any given case must be the result of a combination of clinical experience with an un-

understanding of the physiological significance of the available tests.

For the physician in private practice laboratory tests fall into two main classes. The first consists of those which every educated doctor should be able to carry out, and the second consists of tests which are more difficult in technique and which should be attempted only by a limited number of men who have been able to devote the time necessary to acquire specialized training. Fortunately, the first class is by far the more important of the two.

The laboratory tests which should be at the command of every practitioner of medicine are those which deal with the more important and practically useful examinations of the blood, urine, feces, gastric contents, spinal fluids, pleural and ascitic fluids. These are the tests that are customarily taught in the medical schools in the course in clinical pathology, and the instruction is usually designed to take up the laboratory methods that are absolutely necessary for good practice and those only. An experience in teaching this subject during the last seven years has emphasized the striking fact that in spite of the great contributions which the laboratory has made to clinical medicine there has been surprisingly little change in the character or number of the technical methods which are essential for good practice. In many instances the progress of medical science has resulted in a clearer, broader, and more helpful interpretation of the tests, but the actual technical procedures have not been greatly altered and they are still available to the trained man who has a minimum of laboratory apparatus. It has, indeed, been interesting to find how little new material in the way of technical procedure could justifiably be added to the course from year to year, even though the literature and the practices of various clinics were carefully followed in the attempt to keep the course up to date. The methods for the examination of the urine, for instance, are taught much as they were two decades and more ago. Certain tests, such as urea determinations, have been discarded and others are regarded as having a different significance, but the records still show the color, specific gravity, reaction, albumin and sugar content, and the microscopic examination of the sediment. These simple observations, correctly used and interpreted, are practically all that is necessary in cases of nephritis. The modern "two hour renal test" requires nothing more than determinations of volume and specific gravity, and if it is combined with the phenol-sulphonephthalein test, the technique of which is entirely simple,—the field is open for the study of renal function. It is far more important to understand the significance of these easy tests than it is to worry about the quantitation of blood urea or blood uric acid. The situation is much the same with regard to hematology. The technical procedures of primary value are now as

they have been for years, the counting of white cells and red cells, the estimating of hemoglobin, and the preparation of stained specimens of blood. Quite recently the students at the Harvard Medical School have also been instructed in the methods of counting platelets and of staining reticulated cells, but neither of these procedures involves any essentially new technique. With these, and one or two other tests, such as coagulation time and bleeding time, the field of hematology is open. Again, the technique has been altered but little, and little has been added to it, but modern investigations have brought to it a greater significance. In the examination of the spinal fluid the cell count, which is the most important point, is merely an adaptation of the method of counting blood leucocytes, and not a new technical process. With regard to the examination of the gastric contents, body fluids, and feces the same argument holds true; none of them involves difficult or prolonged examinations or expensive apparatus, and all of them yield information of the highest value to the man trained in their use and interpretation. Here, however, is the crux of the situation. All of these so-called routine tests are easy and consume little time in the hands of a trained man, but they are difficult, time-consuming, and of little value in the hands of an untrained man. What is really needed in the application of laboratory methods to the practice of medicine is not a knowledge of more technical procedures, but a much more exact knowledge of a few technical procedures. Experience has shown that a proper degree of technical skill can rarely be obtained during the medical school course, and it should be the duty of every hospital to see that no house officer receives his diploma unless he has demonstrated an ability to perform satisfactorily all the simpler laboratory examinations and has shown a knowledge of how to use the results in the study of his patient. If every physician was so much at home with the technique of the simpler tests that it was quicker for him to apply them than to wonder whether they were worth while applying, and if he understood how to interpret these tests and gain the maximum information from them, the problem of the relation of the physician to the laboratory would be largely settled.

The second group of laboratory methods having a direct bearing on the practice of medicine consists of those which involve highly specialized technique and complicated apparatus. Electrocardiography, basal metabolism determinations, the Wassermann reaction, clinical bacteriology, and the various types of chemical analysis of the blood fall into this category. The information to be elicited from these and other analogous methods is often extremely valuable, but their application is necessary only in a comparatively limited number of cases. As a whole, these methods do not have the broad general sig-

nificance and importance that characterize the simpler tests just referred to. It is, of course, highly desirable that they should be available to practicing physicians so that they may be used in the cases in which they are particularly indicated, but fortunately there is no necessity for the great majority of physicians to bother themselves about the details of technique. This should be relegated to a small number of men who are devoting their attention to specialized fields. Simplified technical procedures, supposed to be adapted to the use of practicing physicians, are continually being advocated as substitutes for the recognized standard methods employed in performing some of these tests, but they are frequently unreliable or reliable only in the hands of one who has a thorough knowledge of all the sources of error, so that it is far wiser to avoid them and to obtain the dependable observations of experts. The clinician may, therefore, neglect the technical side of these more elaborate tests with a clear conscience, but in so doing he should not feel that he may drop the matter entirely. If he is ever to make use of them—and this the welfare of his patients may demand—he must have an understanding of their significance and of the physiology underlying them. He must know when they are indicated and when they cannot be expected to give important evidence. A little insight into the fundamental principles of metabolism, for instance, and a recognition of the common relationship between increased heat production, pulse rate, and certain other symptoms are of the greatest help in deciding in what cases an observation of the basal metabolism may be of diagnostic significance and in what cases it is entirely superfluous. It is much more important to know in what particular case a determination of the basal metabolism may be of value than it is to know the details of the performance of the test. Then again, the physician should be able to interpret the results of the test in the light of his individual patient. A basal metabolism which is reported as 15 per cent. above normal may or may not be significant, and an electrocardiogram showing a prolonged conduction time may be due to one of several factors, but in either case the physician should not be forced to depend for the interpretation on the man who does the laboratory work and who presumably has a less intimate knowledge of the clinical condition of the patient. The clinician himself should be able to appraise the laboratory findings if the patient is to derive the greatest benefit.

It is frequently alleged that many of our medical schools and teaching hospitals are producing "laboratory men" instead of clinicians. If it is true that the graduates of these institutions enter the practice of medicine handicapped by their dependence on the laboratory, then the system of training is wrong or—what seems more probable—it is imperfectly carried out. When schools and hospitals do their full duty their

graduates will have had an opportunity to study disease intensively, checking and controlling their bedside observations by a variety of exact laboratory investigations. Such an experience will enable them to correlate the clinical manifestations of disease with the underlying physiological processes so that they can subsequently understand and interpret disease without recourse to all the laboratory procedures which were necessary in their student days. They will enter practice trained so thoroughly in a limited number of simple technical methods that they will not hesitate to use them, and they will understand all of their significance. They will also know when more complicated tests are indicated and how to interpret the results. In spite of the extraordinary influence which the laboratory has had on the development of medical science there is as yet no cause for the physician to feel that he cannot keep up with the requirements of the best modern practice. All of the more important elements are easily within his grasp. The need in clinical medicine continues to be, not for men trained in many laboratory methods but for men well grounded in a few methods—not for better technicians, but for better clinicians.

DISCUSSION OF DR. PEABODY'S PAPER.

DR. GEORGE R. MIXOT, Boston: I think that Dr. Peabody has concisely pointed out the relation of the physician to the laboratory. As he has said, the future development is for better clinicians rather than better technicians. Good technicians are, of course, indispensable. Laboratory findings must be considered simply as additional clinical symptoms. They should be used to assist in, rather than to determine, the diagnosis, prognosis or treatment. We must not forget that the patient is the centre of our professional life, and not some isolated data directly or indirectly referable to the individual.

It is not uncommon to see patients who think they have been thoroughly studied and have obtained an undoubtedly correct opinion because they have had an endless number of tests made and have been furnished with extensive reports, often meaningless. In turn, the physician at times seems to feel that "if all the tests are done" then he has overlooked nothing; such a man often gives little attention to the accuracy of the tests and loses sight of the fact that proper interpretation of the results is fundamental. In other words, in utilizing the laboratory, one must use his mind and not make acceptance of dogma. In obscure cases for study, all forms of tests may be justifiable and desirable, but to undertake these blindly is wasteful and useless. Such a procedure without mediation tends to lead one to not making use of our best methods of diagnosis, namely, what we see upon looking at the patient and what he tells us by his own words, together with well-directed questions on our part.

It may be emphasized that the clinician should know the principle of the tests and the nature of the technic so as to appreciate the possibilities of error. He should realize the difference of one man's analysis and report from that of another. The same is true of a roentgen ray examination. Two men may describe the same shadow in the gall-bladder region in very different terms and yet give it the same significance or they may evaluate the finding quite differently.

Figures tend to lead one to a sense of false security. Clinical information is seldom appraised in figures. Laboratory data, on the other hand, is often

expressed in figures which are apt to lead one to the conclusion that such data are final and judgment is not required. This is incorrect, for judgment is often the sole method of arriving at the figure. Likewise, figures presented by a technician must be judged as to correctness and evaluated by the clinician. One is apt to be satisfied with figures and to believe they express exactness, forgetting that when used for certain laboratory data they may vary widely with technique and that they often express only approximate values.

The laboratory examinations in many instances should be made in the light of the clinical findings. Much better laboratory work will be done if, for example, one submits a blood smear for examination, stating that malaria is suspected, rather than simply requesting examination of the smear. The technician should have information regarding the clinical aspects of the case in order to know in what manner to approach the laboratory problem.

One must bear in mind that positive results usually should have clinical evidence to support them and that negative examinations are to be cautiously interpreted and repeated if other clinical symptoms do not agree.

Laboratory examinations are too often exceedingly simple and yet often neglected. A common one to neglect is that of studying the stool by inspection; an examination from which one often can obtain a great deal of information.

If the laboratory examination is reported on incorrectly, it seldom seriously injures the patient. However, there is at least one instance where it may kill the patient, and that is by an incorrect report on the iso-agglutination tests for the selection of a donor for transfusion of blood. One may select a wrong donor on account of improperly made compatibility tests, and as a result the patient may die. However, the proper selection of a donor does not depend solely on the laboratory and technician. The clinician must determine this, for he must decide whether the donor is healthy or has any transmissible disease, whether he can safely give the amount of blood desired for the patient, etc. Therefore, the laboratory does not do all; the final analysis is the duty of the clinician.

LEAD POISONING.

By WADE WRIGHT, M.D., BOSTON.

LEAD poisoning is a disease of increasing importance to physicians. The condition is usually of industrial origin and because of the great variety of trade processes in which some form of lead is used, there are many industrial workers exposed in some degree to the poison.

Cases of lead poisoning which cannot be traced to industrial exposures are not infrequent. Seven per cent. of a large group of cases recently recorded were of non-industrial origin. They may be attributed usually to lead piping of water supplies. During recent months a considerable number of cases has apparently originated in the highly specialized lead piping of condensers attached to unlicensed stills.

Studies made in the Industrial Clinic of the Massachusetts General Hospital showed that nearly 2 per cent. of all patients admitted to the Out-Patient Department were employed at work which exposed them to lead. Of this exposed group about 10 per cent. present evidences of industrial lead poisoning.

Traditionally plumbism is especially common among house painters, but of a large group of

cases of poisoning, house painters constituted but 37 per cent. Various other painting trades, as spray painting, dip painting, and automobile painting, are also responsible for lead poisoning.

Scores of occupations may lead to poisoning. There may be mentioned in connection with structural iron work the jobs of drillers, reamers and riveters; with the rubber industry, compounding, mixers and calenderers; with the printing trades, compositors, linotypers, monotypers and stereotypers; and among other trades, plumbers, steamfitters and gasfitters; sheet metal workers, tinsmiths, electric cable splicers, brass moulders, lead glaziers and handlers of insecticides.

Exposure to lead is so common that physicians may well keep it in mind as a possible explanation of clinical findings of obscure origin when such findings are analogous to those traceable to poisoning by lead.

Despite the fact that lead poisoning has long been studied both clinically and by laboratory methods, there does not yet exist satisfactory and conclusive evidence regarding the mode of entrance of lead into the body and regarding its later disposition in body tissues and organs. Lead is probably capable of entering through the skin, but not in important quantities under industrial conditions. It may be taken in through the nose or mouth and swallowed or be drawn into the lungs. Poisoning can be produced by the introduction of lead through either the respiratory or the alimentary tract, but there is good reason for believing that lead by inhalation is more readily toxic than that received by ingestion.

Laboratory evidence concerning this matter is more valuable than that obtainable from clinical observation of cases originating in contact with various lead dusts as it is obvious that much of the dust drawn in through the nose or mouth of an individual may be swallowed. It is notable, however, that trade processes productive of lead-laden dusts are more hazardous than those with which dust is not associated.

There is probably no recognized poisonous agent which is not known to exert its toxic effects in varying degree upon different individuals. Varying susceptibility to lead is strikingly manifested among lead workers. Cases of poisoning have been reported after exposure of but a few days, while many men have worked with apparent safety through long terms of service in contact with large quantities of some form of lead ordinarily considered dangerous. It is probable that this idiosyncrasy may be at least in part explained through careful observation and examination of persons relatively immune to lead. Considerable evidence exists pointing to a much greater susceptibility to lead among women than among men.

One group of cases of lead poisoning studied showed an average duration in trade, at the time of diagnosis, of nine years, two months.

It is not possible to state with accuracy the average period of exposure prior to the onset of poisoning, for lead poisoning is usually insidious in its development.

It is apparent that an individual may take into his body considerable quantities of lead and yet present no symptoms or signs which suggest lead poisoning or warrant such a diagnosis. It is conceivable that all persons exhibiting such evidence of lead absorption as a lead line on the gums are in some degree affected by the presence of the metal in the tissues, but as a matter of practical judgment physicians must at present recognize the existence of lead absorption without determinable poisoning. It is an issue of medico-legal importance because of its bearing upon decisions under workmen's compensation acts.

The manifestations of lead poisoning are many and varied. For years the popular medical conception of the disease concerned little more than colic, constipation, wrist drop, the blue line and basophilic stippling of red blood-cells. Though these signs are frequently encountered, they do not fairly constitute a clinical picture of the disease. Few disorders present as diverse a symptomatology as lead poisoning. There is no characteristic syndrome. Certain symptoms and signs are, however, more frequently encountered than others.

Abdominal pain is usually noted. This pain is cramping in character and localized most commonly in one or both lower quadrants or about the navel. It is much less often epigastric. It may be almost constant over periods of hours or be of short duration. It seems to bear no relation to meals. Chronic constipation is reported in most instances. Diarrhea may exist but is rare.

Vomiting occasionally occurs in severe and especially in relatively acute cases. Epigastric distress, nausea and eructations are common. The appetite usually is poor, but failure of the appetite, contrary to a prevalent impression, is not a reliable early sign of poisoning. Loss of weight is of importance. There is often progressive loss antedating the onset of evidence of disease recognized by the patient. A sense of tiredness and general weakness is an almost invariable complaint.

Symptoms of cardio-respiratory disease are generally associated with evidences of nephritis. Arteriosclerosis is said to be caused by lead poisoning. It is certainly often observed, as is also chronic nephritis. An acute nephritis is unusual, but may be observed in cases of comparatively acute poisoning.

Affection of the nervous system is very common in lead poisoning. In many cases there is early impairment of the memory. Disturbances of vision exist, though rarely. Headache and dizziness are often present. Loss of consciousness and convulsions may be caused by lead and usually lead to a diagnosis of epilepsy.

Somewhat indefinite pain in the muscles, as of the thighs or arms and of the back, is common. Pain in the joints, especially of the knees and elbows, is an important and usually early symptom. Gout, associated with lead poisoning, in painters is possibly directly related to the effects of turpentine and has been observed in a small percentage of cases. Bursitis is not infrequent. Numerous cases of elbow pain in connection with lead poisoning have been studied in the Industrial Clinic of the Massachusetts General Hospital. In a few instances the pain was closely localized to the external epicondyle of the humerus, but the majority showed tenderness on pressure over the head of the radius, the site of a bursa described by Dr. Robert Osgood.

Physical examination of cases of lead poisoning may reveal but few definite signs of the disease.

There is customarily some degree of pallor, often of a grayish hue in well marked cases. It is possible that the characteristic pallor is not due alone to anemia but also to vasomotor changes. Marked pallor may exist in the presence of a comparatively high hemoglobin content of the blood. Loss of subcutaneous fat and progressive wasting are usually noted as the disease advances.

The eyes show, rarely, evidence of paralysis of the muscles. Retinal changes may produce the picture of albuminuric retinitis. Eye reflexes are not affected.

A blue line in the gums has been considered by many physicians as evidence of lead poisoning. It is not, however, a pathognomonic sign. Blue lines may be produced by other metals than lead, such as mercury, and even in a lead worker, the blue line of itself signifies only exposure to lead and lead absorption. There can be no doubt that many well defined lead lines are overlooked in routine physical examinations. Gums which upon casual survey show no abnormality may disclose upon careful examination a fine dotted blue-black marking near the dental edge of the gum, a line often rendered readily visible when the edge of the gum is gently rubbed with a piece of gauze to remove epithelium, food particles and pus, and a hand lens employed, with good illumination.

The heart is not involved in most cases of mild lead poisoning. With advanced arteriosclerosis, cardiac changes incident to such a condition may be noted. Slowing of the pulse rate during attacks of colic is occasionally marked.

The examination of the abdomen usually results in negative findings. Tenderness other than that ordinarily related to constipation is not common. Even during attacks of colic pressure on the abdomen affords relief rather than causes pain.

Early in the disease there usually develops weakness of the extensor muscles of the forearm, more marked in the arm most used at work.

Though other groups of muscles may become affected, this antibrachial type is the most common form of paralysis. Complete wrist drop is a classic sign of lead poisoning, but it is very rarely seen at the present time. Paralysis of the Aran-Duchenne type, affecting the interossei and the thenar and hypothenar groups is unusual, as is the peroneal type of paralysis.

The blood picture of lead poisoning is that of a more or less severe secondary anemia, a hemoglobin ranging from 85% down, a red blood count diminished but seldom to less than 2,000,000 cells per cubic mm. Basophilic stippling of red blood cells, while observed in other forms of anemia than that due to lead poisoning, is an important finding, particularly when coupled with other evidences of lead absorption or poisoning.

Though a slight leucocytosis may exist in early cases, it is not strikingly evident during the course of most cases of lead poisoning. Certain writers attach much importance to a relative or absolute increase in the numbers of lymphocytes and large mononuclear cells. A slight eosinophilia is not uncommon.

Examination of the excreta of cases of lead poisoning may reveal the presence of lead in either the stool or urine or in both. In suspected cases it must be remembered that lead in the stool is not absolute evidence of lead absorption. Reports of a chemical examination should be regarded as authoritative only when the determinations have been made by a thoroughly competent chemist or technician, for it has been learned that many of the available analytical methods are not reliable when utilized for the determination of lead in organic mixtures such as urine and feces.

The continued excretion of lead is not adequate evidence of continued poisoning, neither is a negative chemical report adequate evidence of the absence of lead in body tissues.

In summarizing the more important elements in the recognition of lead poisoning there may be considered: a history of known or probable lead exposure, evidence of the presence of lead in the body such as a lead line or lead in the excreta, abdominal pain, constipation, anemia, stippling of red blood cells, joint and muscle pain, weakness, and partial or complete paralysis, usually of the extensor muscles of the forearms.

Unless far advanced the prognosis in cases of lead poisoning is excellent for improvement and very fair for recovery. Cases with advanced paresis seldom regain full function, those showing marked mental symptoms with persistent headache do not do well. The ordinary mild case with constipation, occasional colic and moderate muscular weakness, under proper treatment, recovers completely.

The fundamental treatment of lead poisoning so far as it is rational is based upon our limited

knowledge of the mechanism of the elimination of lead.

Active kidneys and bowels offer the best assurance of progressive improvement in most cases. A useful routine remedial agent is magnesium sulfate, used in small doses over many days, with occasional free intervals. Potassium iodide is considered of possible value but its worth is not proven. Electrolytic baths have been suggested but their effectiveness is questionable.

Severe colic may be relieved by morphine or by the use of amyl nitrite or nitroglycerine. Atropine is also recommended.

Iron is used in cases of marked anemia and various drugs for the palliative treatment of rheumatic pains.

Electrical treatment, massage and exercises are advocated for the restoration of seriously affected muscles.

Most of the lead poisoning which exists is preventable. Many of the trade processes which are hazardous because of the presence of lead could be rendered far less dangerous than they now are. Lead poisoning is not only a common ailment but the prolonged disability which it causes is productive of a lamentably great total of distress and economic waste.

While the safeguarding of trade processes is not a function of the medical profession, the recognition of disease assuredly is. Until physicians recognize in persons exposed to lead the evidences of lead absorption and of poisoning, the dangers of hazardous trade processes will not be appreciated. Only through the help of physicians can susceptible individuals be identified and removed from danger. Only with competent medical counsel can this most important of the industrial diseases be controlled.

DISCUSSION OF DR. WRIGHT'S PAPER.

DR. JOHN A. KEY, Boston: Dr. Wright has covered the industrial and clinical aspects of this condition, and at his suggestion I will confine my remarks to the pathological aspects. The literature on the pathology is voluminous, mostly in German, French and Italian, and mostly from the experimental standpoint, because lead poisoning, as Dr. Wright has said, is a disease which disables and does not kill, and autopsy reports are rather meagre. Just as the literature is voluminous, it is also varied: That is partly dependent on the manner in which lead was given, partly dependent on the time in which it was allowed to act, and partly dependent on the tissues in which each investigator was most interested.

In regard to the pathology of the intestinal colic, there is nothing definite known. Various writers have described degenerations in the coeliac ganglion and also in the plexuses of Meierbach and Meissner in the intestinal wall. Other investigators feel that the colic is due to the direct action of the lead on the smooth muscle, causing contraction. Clinical evidence that lead acts on smooth muscle is evidenced by the action of lead on the uterus and the fact that miscarriages and abortions are frequent in women who are exposed to lead.

The absorption is probably nearly always through the gastrointestinal tract. That is true just as much of lead workers exposed to dust as it is in men who are not exposed to dust. The possibility of absorp-

tion through the skin has been tested experimentally, and by rubbing large amounts of lead over the skin for periods of ten to 25 days in animals only very minute amounts of lead have been obtained upon analysis of the animals afterwards. The loss of weight is characteristic and early and often appears before any other symptom. It is in part due to loss of appetite, but it is believed that lead has some effect on the general nutrition. What that is, is not known.

Lead absorbed through the gastrointestinal tract is first brought to the liver, and its effect on the liver is evidenced by focal necroses. In chronic poisoning there is a fibrosis. This is not a true cirrhosis but is rather the necrosis of the parenchymal cells and the late replacement of this area by fibrous tissue. The nephritis is in the acute stage of the parenchymatous type; that is, Ophuls has described degenerations in the distal ends of the convoluted tubules. In the chronic cases it is an interstitial nephritis, and it is questionable whether it is not due to the effect on the blood-vessels, there being at the same time a thickening of the walls of the glomeruli. The arteriosclerosis is a common autopsy finding in men who have been exposed to lead over long periods, whether or not they had been clinically cases of lead poisoning. Experimentally I don't think it has ever been produced in animals. In the French literature there is some evidence of the production of arteriosclerosis, but the reports don't bear very close scrutiny and their explanation is that it is produced by a hypertrophy of the adrenals. However, the hypertrophy of the adrenals when found in lead poisoning is a hypertrophy of the cortex.

Paralysis is usually manifested in muscles which are used most; that is, a man who uses his thumb and finger muscles exceedingly is more apt to get thumb palsy or finger paralysis than he is to get a wrist-drop. In the muscles affected there is a secondary degeneration and atrophy. In the nerves there is typical Wallerian degeneration; and in the anterior columns of the cord there is a degeneration of the nerve cells. It is questionable which is primary and which is secondary, the peripheral or the central injury. In the encephalopathies autopsy reports show a pale brain which is usually somewhat shrunken. Microscopic sections have shown for the most part only infiltration around the blood-vessels. In a few cases there are reports of degeneration of the nerve elements. In regard to the muscular pains and the arthritis and neuritis, as far as I know, there are no pathological reports. As a whole, the pathology seems to be shown that lead may attack a wide variety of tissues and cause a parenchymatous change which is later followed by fibrosis. The blood changes are secondary anemia which progresses with the continued absorption of the lead. Usually well-defined lead poisoning is present before the blood count goes below three million, and the patient sees the doctor. It may go on to a severe anemia which resembles a primary anemia or it may go on to an aplastic stage. The hemoglobin index is less than one except in severe cases of anemia where it may be more than one. There is usually a mild leucocytosis which is usually more in the nature of a lymphocytosis, there being a relative and absolute increase of the lymphocytes and of the mononuclear elements. Some authors lay emphasis on the lymphocytosis and others on the mononuclear increase. In some cases the polymorphonuclears are absolutely increased. Apparently lead in the blood stream destroys the polymorphonuclear leucocytes and the red blood cells. Evidence of the destruction of the polymorphonuclear cells is seen in the numerous degenerative forms in the smear. Evidence of the destruction of the red cells is seen in poikilocytosis and in anisocytosis, and in sections of the bone marrow, spleen and lymph glands large numbers of fragmented red cells are found in the endothelial cells. The bone marrow is active.

I think the anemia isn't due to a depression of the bone marrow but due to a destruction of the red cells. The active regeneration in the bone marrow

is evidenced by a high reticulated red count or the presence of numerous polychromatophilic cells or stippled cells. If one compares the percentage count of the polychromatophilic cells and the stippled cells with the reticulated cells, the reticulated count is equal to the sum of the other two. That means from the reticulated count we cannot diagnose stippling because it is obscured by the vitally stained network. I regard the stippled cell as an abnormal young cell. It is a red cell in which small basophilic particles are present. These are quite different from the Howell-Jolly bodies which are derived from the nucleus. The basophilic particles are protoplasmic elements, and while they are not confined to lead poisoning, they are nearly always found if a careful search is made. They are also present in pernicious anemia, pseudoleukemia and in almost every secondary anemia of toxic origin and in anemia following hemorrhage in which hemoglobin is retained in the organism. A number of authors state that stippling is uncommon in lead poisoning. These reports reflect on the ability of the man who looked for them. For instance, Schnitter in 1914 studied the blood from 283 cases and in 239 of these he found stippling, but in the last 88 cases in which his technique was improved he found stippling in 100 per cent. He and other writers in the German literature lay emphasis on the fact that in looking for stippling in the blood smear one should beware of a counter stain. They declare that in the Wright stain or in any other Romanowsky stain the eosin obscures the stippling. So they recommend a single stain of methylene blue.

THE TREATMENT OF RHEUMATIC FEVER.

By HOMER F. SWIFT, M.D., NEW YORK, N. Y.

[From the Hospital of the Rockefeller Institute for Medical Research, New York City.]

The treatment of a sick patient depends largely upon the physician's conception of his disease. This is especially true if treatment consists not merely in alleviating pain or other unpleasant symptoms, but is directed towards increasing the patient's power to master the malady. It is well to recall that in all general infections there is a constant struggle between patient and infectious agent, and that recovery is usually brought about by an increase in the defensive mechanism of the host, while a downward course is evidence of a failure of these defensive agencies to keep pace with the inroads of the parasite. At times the struggle between these two antagonists is quickly terminated; the outcome is soon known; either recovery or death closes the picture. We witness an acute disease. Another degree of intensity gives us a chronic infection; the host has not sufficient strength completely to subdue the parasite, but the constant cohabitation of the two contestants is of such a nature that the struggle is prolonged; on the one hand, the various defensive agencies of the body are slowly mobilized so that the parasite is either killed or rendered harmless by encapsulation; on the other hand, conditions may be slightly in favor of the infectious agent and there follows either a continual destruction or an abnormal overproduction of certain tissues of the host. In other instances the clinical picture shows successive periods of advantage

on one side and then on the other; the balance is often so fine that the slightest depressing influence upon the patient may permit the recrudescence of symptoms.

By suitable treatment the pathogenic properties of the virus may be kept at a level so low that ordinary diagnostic measures fail to detect its activity. It is entirely conceivable—even highly probable—that drugs or other parasitstatic agents may be sufficiently powerful to depress the virus to such a degree that it may be somnolent but not moribund; withdrawal of the drug may permit it again to resume its nefarious work. It is possible, moreover, that a drug may prevent the virus from acting on one organ or set of organs and still be powerless to suppress its activity elsewhere. Thus the clinical picture of the disease may be so altered that it is difficult or impossible to recognize it as a condition analogous to that presented by an untreated patient.

The consideration of latency of infectious agents is one that would require much time to discuss fully. It is a most important phase of many diseases. Because of an increase of the patient's natural defenses the virus may be encapsulated, but remain living and capable of resuming its pathogenic activity should the immunizing tissue be destroyed or other inhibitory agencies be depressed as the result of another disease. Again it is well recognized that a microorganism such as the *Treponema pallidum* may lie latent in tissues for long periods without exerting any demonstrable local destructive action, or inciting the usual cellular response; then, as a result of a lowering of the patient's general resistance, or because of a local trauma, lesions characteristic of syphilis may be produced. Similar examples might be cited in other infections. As one studies his patients over years he is more and more impressed with the probability that recurrences in many diseases are due to renewed activity of infectious agents that have lain latent in the tissues for months or years.

The various possibilities just mentioned must all be carefully weighed in considering rheumatic fever, its complications and sequelae. Unfortunately, we do not know the specific etiologic agent. Our classification of the various conditions included under the term, rheumatic fever, rest therefore upon a study of symptoms and signs, upon the peculiar course of these manifestations, upon the response of some of them to certain drugs, and, finally, upon characteristic histopathological alterations in certain organs. It is possible that our conception of the nature of this disease may be entirely altered by new discoveries; on the other hand, if we may draw an analogy from the history of the study of syphilis, it is probable that the discovery of a definite etiologic agent or the demonstration of characteristic immune reactions would extend the picture rather than alter entirely the notions

already extant. Thus clinical study pursued with new methods as well as old will bring us nearer to a true picture of the relationship existing between the various manifestations in different cases.

In recent years an altered point of view towards this disease is reflected by the change in the name from acute inflammatory rheumatism, acute arthritis, or polyarthritides rheumatica, to rheumatic fever. It is evident that high fever, profuse perspiration, marked general intoxication and acute migratory polyarthritides responding to salicylates do not give us a complete picture of the disease; less obvious manifestations point to involvement of important viscera. For example, we now recognize that certain symptoms and signs, of themselves relatively insignificant, but important when considered in relationship to the general infection, indicate active disease in the heart. These are recurring fever and rapid pulse rate without renewed arthritis or evidence of complications in other organs; precordial pain and tenderness, and areas of paraesthesia in the so-called cardiac lead's zones; dyspnea and orthopnea in adults, and in children an increased respiratory rate unexplained by pneumonia or pleurisy; increased area of cardiac dullness; abnormal cardiac rhythms such as partial and complete heart block, auricular fibrillation, and tachycardia. Daily electrocardiographic studies of all of our rheumatic fever patients have convinced us that these symptoms and signs point to actual disease of the myocardium. Rarely is there instrumental evidence without accompanying clinical signs of cardiac abnormality. It is noteworthy that the majority of our patients minutely studied in the past three years show definite bedside and electrocardiographic evidence of myocardial involvement. If we add to this the long-known tendency for rheumatic fever patients to develop endocarditis and pericarditis, it is evident that most persons suffering from *polyarthritides rheumatica* also have *carditis rheumatica*.

In children and adolescents with rheumatic fever, arthritis is often so slight and transitory that it may be easily overlooked, and the entire picture be one of visceral involvement. Recently a child died in the Presbyterian Hospital with symptoms of acute heart failure. We were unable to obtain a history or other evidence of any of the usual rheumatic manifestations; microscopic examination revealed acute rheumatic myocarditis with many characteristic Aschoff bodies; no endocarditis or pericarditis. There is evidence, therefore, that the virus can attack the heart alone and allow all of the other organs to escape injury. Many children with chorea have no fever, or one only of low grade, and show clinical evidence of active cardiac disease; post-mortem examinations reveal histopathological evidence of rheumatic myocarditis and endocarditis. Others may have, in addition,

characteristic subcutaneous nodules, or there may be only nodules and carditis. Our present belief is that these various combinations of the rheumatic series (Cheadle) in childhood point to activity of the unknown virus in the body just as certainly as if there were a migratory polyarthritis. Other less distinct indications of probable continuing rheumatic infection during childhood are repeated attacks of tonsillitis, enlarged tonsils and satellite lymph nodes, growing pains, and certain cutaneous manifestations.

Failure to recover weight lost during the first weeks of illness or continuous loss of weight are presumptive evidence of persistence of infection. In recent years we have weighed all patients daily, and compared their weight charts with other signs and symptoms. Not only in children, but also in adults have we repeatedly observed that stationary weight below that usual for the patient is attended by slight fever, recurring arthritis or evidence of carditis; relapses have usually been heralded or accompanied by additional loss of weight or by a cessation of increase ordinarily evidenced by a recovering patient. A steady gain in weight does not necessarily mean that the patient will not suffer a relapse, but the liability is much less than in the presence of a subnormal, stationary, or falling weight. In this respect, rheumatic fever may be compared to tuberculosis. It has long been recognized that the acute stages with high fever and painful polyarthritis are attended by a rapidly developing anemia and emaciation. Clinicians who studied the disease before the introduction of salicylates describe the starved appearance of rheumatic fever patients who remained in the hospitals for months. Fortunately, the drugs at our disposal prevent most patients going into such a cachectic state; but the majority of them display a similar tendency which is masked unless we follow the weight curves. The loss of weight may be due to several causes: Du Bois and his co-workers have shown that fever *per se* increases the basal metabolism in a very definite manner. In severe infections the toxic state leads to a rapid destruction of body protein. A rough parallelism between the level of basal metabolism and the pulse rate has been demonstrated by several observers. Frequently the pulse of patients with rheumatic fever remains rapid after the fever has disappeared. In many instances this persistently high pulse rate is evidence of a continuation of myocarditis, and suggests that the virus is still active. Thus we may regard a high pulse rate as an indication for rest, and also for increasing the patient's food intake.

Leucocytosis is another important sign of continued infection. It has long been known that leucocytosis was a feature of this disease, and that invasion of new joints or organs was accompanied by an increase in the number of white blood cells; there are numerous observa-

tions that the number of leucocytes falls after the exhibition of sufficient salicylate to eliminate the arthritis and fever. Lately we have been making leucocyte counts of all our patients several times a week, and have been impressed by the fact that after the initial fall in leucocytes accompanying the administration of salicylates or neocinchophen, there is often a recurring leucocytosis which persists in spite of continuing the drug in sufficient doses to keep the temperature normal and the patient free from pain. In order to test the meaning of this sign, patients have been treated in different ways and the result noted.

Our studies now indicate that leucocytosis is an evidence of a persistent infection, and also confirm the opinion derived from other observations that the salicylates and neocinchophen do not completely destroy the virus, but suppress it sufficiently to relieve many of the characteristic symptoms of the disease.

This leads us directly to a consideration of salicylic acid with its numerous derivatives; later, compounds of phenylethylcholinic acid will be discussed.

From the clinical viewpoint probably no more striking therapeutic effect has been seen than that following the introduction of the salicylates for the treatment of acute articular rheumatism. The results were marvelous; intense suffering was relieved, and the distressing sequelae incident to continued high fever and prolonged intoxication were eliminated. The failure to elicit a similar response in patients with other conditions led to the opinion that salicylic acid was a specific for acute inflammatory rheumatism. The activity of synthetic chemists has resulted in numerous derivatives; drugs less irritating to the gastro-intestinal tract than the crude salicylic acid or sodium salicylate, but all dependent upon the salicyl ion for their specific action. Pharmacologists have shown that in common with many coal tar compounds, the salicylates have an antipyretic action due to increased heat elimination. They also are analgesics, they lessen pain in many conditions, both non-rheumatic and rheumatic. But the disappearance of the signs of the inflammation,—swelling, heat, redness, and tenderness,—so strikingly evident in the joints of rheumatic fever patients following the exhibition of large doses of salicylates, is not seen in patients with arthritis of known bacterial origin, nor in animals with experimental arthritis. The so-called specific action of the drug is, therefore, unexplained. This is not surprising when we realize that the etiology of rheumatic fever and the exact nature of the arthritis are unknown. Certain observers have claimed that the anti-phlogistic effects of salicylates demonstrated in the arthritis of patients with acute rheumatic fever are not specific. By means of special charts, wherein all of the symptoms and signs of inflammation in each joint are noted daily,

we have recorded in many cases the results following the administration of therapeutic doses of salicylates; many of the patients have been observed for varying periods before administering the drug; the evolution and resolution of the inflammation in each single joint and in all of the joints have been followed; repeatedly we have recorded the sudden disappearance of inflammation in recently invaded joints and as striking a cessation of the tendency for new joints to be involved. At the same time we have failed to observe a similar antiphlogistic effect in patients with gonorrheal rheumatism, or arthritis due to other bacteria; patients with serum disease arthritis, likewise, have not been relieved by large amounts of salicylates. These observations are not unique, nevertheless they are of distinct value because made with a definite point of view: to prove the specific antiphlogistic action of salicylates upon the arthritis of rheumatic fever patients.

The therapeutic and toxic doses of salicylates approximate one another. Failure to recognize this fact often results in failure to allay pain. Frequently we have admitted patients who have been taking 0.6 to 1.0 gram (10 to 15 grains) doses of sodium salicylates or aspirin three or four times daily with only partial or no alleviation of their symptoms; subsequent rapid administration of the same drug to a point just below toxicity has afforded complete relief.

The physician should be thoroughly familiar with the symptoms and signs of toxicity: tinnitus aureum, deafness, nausea, vomiting, flashes of light; in extreme instances, delirium; injury to the kidney resulting in hematuria and diminished renal function are occasionally seen if the drug is given too freely. Hanzlik and his co-workers have laid special emphasis upon renal poisoning, and claimed that many of their patients had a temporary gain in weight after receiving amounts of sodium salicylate sufficient to relieve their arthritis and fever. We have repeated these experiments but failed to observe such marked evidence of renal injury, either in the form of severe albuminuria, cylindruria, hematuria, or evidence of an accumulation of edematous fluid in the patient's subcutaneous tissue. Gain in weight in practically all instances could be explained upon the basis of replacement of water previously lost by excessive diaphoresis. Rarely, when salicylates have been given in large amounts, we have seen edema of the extremities and a sudden increase in weight; but in such cases it was subsequently evident that too much had been administered. Our rule is to prescribe the drugs in 1 to 1.5 gram (15 to 22 grains) doses every hour until pain is alleviated or the first toxic symptoms appear—usually tinnitus or nausea; ordinarily from 6 to 12 grams (90 to 180 grains) are sufficient. The drug is then discontinued until the following day when a total amount of from one-half to three-fourths of the toxic dose is ordered.

Depending upon the severity of the case and the therapeutic results the drug is continued in this quantity for longer or shorter periods, and subsequently the daily total is slowly reduced. We have found that an hourly chart on which are noted the therapeutic and toxic effects of the drug for the first two days, and a daily chart on which the joint symptoms, temperature, and pulse rate are recorded have been of great value in helping us determine the correct dosage for each patient.

Individualizing in the administration of salicylates to rheumatic fever patients is most important. No absolute rule can be given except that of studying each patient during each course of treatment. We have seen the toxic dose vary between 6 and 10 grams for the same individual at different times. An even wider range is seen in different individuals. Men, as a rule, tolerate larger doses than women. The body weight of the patient probably bears some relation to the toxic and therapeutic dose.

The beneficial effect of practically all of the numerous derivatives of salicylic acid is more or less proportional to the salicyl ion content. Improvements in forms of the drug concern themselves mainly with compounds that are less irritating to the gastro-intestinal tract. Crude salicylic acid is most irritating and practically never given; sodium salicylate is less irritating but often is repulsive because of its peculiar taste. Acetylsalicylic acid having a sour taste is often better tolerated. The list of salicyl derivatives is too long to describe in detail, and is probably much larger than necessary. Numerous preparations have been introduced to the profession by enterprising drug manufacturers with glowing testimonials. Had physicians been well acquainted with the technique of using sodium salicylate and acetylsalicylic acid properly they would rarely have been compelled to resort to more unusual and expensive derivatives of salicylic acid in the treatment of patients suffering from rheumatic fever. There is no doubt that certain patients can tolerate therapeutic doses of acetylsalicylic acid when they cannot bear sodium salicylate; the reverse is also true. Cases are also seen where other derivatives appear to be better tolerated; but often it will be found that the apparent diminution in toxicity is due to a lower salicyl content of the preparation in question; and the therapeutic effect is proportionally less.

Attention has already been drawn to certain actions of the salicylates. It is important to realize that we do not know the real reason for the so-called specific effect, although there has been much speculation and some experimentation on this subject. Hanzlik and his co-workers have shown that the salicyl ion does not exist in any greater concentration in the joint fluid than in other tissues, and also that it probably does not exist as free salicylic acid in arthritic exudates. Boots and Cullen have found that the

reaction of joint exudates from patients with rheumatic fever is always alkaline, so that free salicylic acid cannot exist in these exudates even though large amounts of salicylic salts were present. The anti-arthritis effect cannot, therefore, be due to free salicylic acid.

Some experiments of mine indicate that during immunization animals receiving sodium salicylate in doses comparable to the largest therapeutic doses for patients produce somewhat smaller amounts of immune bodies than do controls similarly immunized but not receiving salicylates. This suggests that possibly this drug acts by depressing the susceptibility of the animal to the antigenic stimulus of the foreign protein—both bacterial and non-bacterial. In another series of experiments by Boots and myself, salicyl treated rabbits with experimental arthritis induced by intravenous inoculation of green streptococci had fewer purulent joints than did a corresponding number of non-salicylated controls. Both groups of animals had a similar number of inflamed joints; the smaller amount of purulent arthritis among the salicyl treated animals suggests that in some instances, at least, the drug decreased the irritating power of the bacteria in joints even though the joints were infected. This suggests that the action of salicyl in the animal body may be bacteriostatic even if it is not actually bactericidal.

Such an action corresponds with the observed effect in patients with rheumatic fever. The persistent leucocytosis, the continuation of signs of myocarditis, the development of endocarditis and pericarditis in patients under the influence of salicylates, and the liability for many patients to have relapses when the drug is reduced too rapidly or discontinued too soon, all indicate that its chief action is to reduce the intensity of the pathologic process rather than to destroy completely the virus. It seems to us that this reduction in intensity of the disease relieves pain, spares the patient, and permits a more rapid convalescence.

Such effects might lead to harmful therapy if not well understood and considered in the general management of the patient. Relieving certain distressing symptoms and lessening others so that the patient feels almost well may lull both the sick man and physician into a false sense of security. Very frequently I have seen patients who, while taking 2 to 5 grams (30 to 75 grains) of sodium salicylate or aspirin daily have been discharged from a hospital, and after a few days at home without the drug have developed relapses of varying intensity. According to our present opinion such patients were suffering the entire time from the disease, but were unconscious of its ravages; they were, therefore, subjecting themselves to stress and strain beyond a proper point, and losing the benefit of the time already spent in the hospital, and increasing their liability to serious visceral complications. Under such circumstances it is

questionable whether the administration of drugs may not do more harm than good. This statement is not an indictment of anti-rheumatic remedies but rather a common method of using them.

Recently phenyleinchoninic acid and its derivatives have been introduced for the treatment of rheumatism.* Derivatives of quinolene, they were first used for the treatment of gout. Although unrelated, both salicylic acid and phenyleinchoninic acid have been found to increase the permeability of the kidneys for several non-protein nitrogen waste products; both are antipyretics, and both decrease the signs of inflammation in the joints of rheumatic fever patients. We have found that einchophen and neoinchophen act against the signs and symptoms of rheumatic fever in much the same manner as do the salicylates. Einchophen is liable to induce severe gastric distress in patients taking enough to relieve their arthritis and pyrexia. Neoinchophen, on the other hand, has been free from this unpleasant by-effect, and has been given in daily total doses of from 0.1 to 0.15 of a gram per kilo body weight without severe demonstrable toxicity. All of the remarks already made in reference to the therapeutic action of the salicylates can be applied to drugs of the einchophen series: they combat certain unpleasant symptoms, but clinically do not seem to destroy the virus completely, as many patients have continued to have a leucocytosis while under their influence and others have developed relapses upon discontinuing the drug. Similar to our experience with both sodium salicylate and aspirin, we have occasionally seen patients continue to develop new symptoms and signs while taking therapeutic quantities of neoinchophen, and experience marked relief when another anti-rheumatic remedy was substituted. Neoinchophen is a useful adjunct to our therapeutic armamentarium, but up to the present has not been proven a substitute for the salicylates. Each drug at times is useful in replacing the other, when the one first tried is either too toxic or fails to induce the proper therapeutic effect.

No satisfactory serum has been devised for the treatment of patients with acute rheumatic fever. This is not surprising in view of our ignorance of an etiologic agent with which to immunize animals. It now seems probable that the favorable results from anti-streptococcus serum injections reported several years ago were similar to the recoveries seen following the injection of other forms of foreign protein.

Patients with all types of arthritis have been treated by intravenous or intramuscular injection of killed bacteria, various colloidal substances, or other foreign proteins in various forms. Typhoid vaccine seems to have been employed more than other foreign proteins. In

*Atropian was the name first used, but during the war the term einchophen was adopted. Similarly, neo-atropian was changed to neo-einchophen. Another trade name is tolysin.

order to obtain satisfactory clinical results it is necessary to induce a severe chill, followed by fever, symptoms of marked general intoxication and to stimulate a high degree of leucocytosis. Similar treatment has been employed in most general and local infections as well as in the treatment of arthritis. It is now recognized that there is nothing specific in this form of therapy; that when improvement follows it appears to be due to a sudden mobilization of leucocytes, and possibly other defensive agencies. Many observers who claim the most favorable results from intravenous injections of bacterial vaccines into rheumatic fever patients report only an improvement or disappearance of the arthritis, and an antipyretic effect; they do not mention whether the other symptoms of the disease disappear or not. All agree that the toxic reaction is too severe to warrant the general introduction of this form of therapy, and advise that it be reserved for those patients who do not respond favorably to the salicylates. We have not attempted to repeat the observations of others because we felt that because of the non-specific nature of the reaction it would not help greatly in the elucidation of our problem of the nature of rheumatic fever, especially when such marked benefit can be obtained from drugs.

No discussion of treatment would be complete without mentioning the question of tonsillectomy or the removal of other foci of infection. There can be little doubt that there is a relationship between tonsillitis and rheumatic fever; the exact nature of that relationship is another question, and one we shall not take up at this time. The proper removal of diseased tonsils is often followed by marked improvement in patients who are suffering from chronic forms of this disease. Even from the most conservative point of view, in which it might be claimed that tonsillitis is not "rheumatic" in nature, it would seem advisable to remove simple diseased tonsils, or tonsils that were the point of origin of other general infections. Even more, then, would one advise tonsillectomy if he believes that diseased tonsils are directly responsible for an attack of rheumatism. It is, however, well to bear in mind that many relapses occur in individuals who have had their tonsils well removed, and to warn patients of this possibility in advising operation.

Summary: Within the limits of this paper it has been impossible to consider the treatment of the various important complications of rheumatic fever, or to give specific directions for the use of the remedies discussed. An attempt has been made rather to summarize our present conception of the disease as an infection lasting longer than is ordinarily believed, to show that only certain of the well-recognized symptoms yield readily to anti-rheumatic drugs, and that these drugs often simply depress or mask the activity of the virus. In general, it is important to recognize what our remedies fail to do as well

as what they do. Proper treatment consists not only in administering anti-rheumatic drugs, injecting foreign protein, or removing possible points of focal infection, but also in prescribing rest, guarding the heart against over-strain, regulating exercise, attending to the diet, and in devising measures to increase the patient's general resistance against infection.

DISCUSSION OF DR. SWIFT'S PAPER.

DR. ROGER I. LEE, Cambridge: I think we will all agree that we have had a splendid paper that has given us an adequate résumé of the treatment of rheumatic fever. What Dr. Swift didn't say—he was too modest to say—was that many of his statements are completely backed by his own experimental work in the laboratory. Dr. Swift is combining his clinical studies with his laboratory studies, and it is a piece of work that represents the best that there is in internal medicine. To some of us it is particularly gratifying to find that his carefully made conclusions agree with our own less carefully made conclusions at the bedside. For example, it has always been a pet phrase of mine that there was no specific in rheumatic fever, that salicylates weren't a specific, but that rest and salicylates properly given came near being a specific in rheumatic fever; and I think that Dr. Swift has come to practically the same conclusion. We are dealing with a self-limited disease, although its self-limitation isn't so sharp as in the infectious diseases. We have the asset of self-limitation, we have the asset of salicylates and we have the asset of rest; and these three assets give us in a measure a control over the disease.

I liked Dr. Swift's insistence on the point that after you have apparently aborted the disease, you were still on very dangerous grounds, and I would like to emphasize, as he has emphasized the salicylates, the importance of rest in preventing relapses. It has been our experience in the hospital that patients who have come in after taking the salicylates up to the toxic dosage without much benefit are often promptly relieved under hospital conditions, where rest can be made nearly absolute.

I was also glad to find that Dr. Swift in his studies had difficulties with the obstinate case. That agrees with our phraseology of "almost a specific," because there are cases that are obstinate under the best of treatment, and those cases do not seem to give way to any form of therapy. However, a properly applied therapy will minimize those, and we only have the inevitable case that occurs in every infection.

A MEMBER (LADY): I would like to ask Dr. Swift what he does when sodium salicylate produces nausea.

DR. SWIFT: We have regarded nausea following large doses of salicylates as central in origin. Some patients, on the other hand, find sodium salicylate repulsive because of the sweetish taste; in such cases, switching to aspirin is of benefit. Occasionally a patient is seen who cannot take more than ten to twenty grains of either drug without nausea, or other toxic symptoms; in such cases neo-einchophen is most useful.

A MEMBER: Do you employ salicylic therapy when there is endocarditis, without joint symptoms?

DR. SWIFT: If there is simply a low-grade fever we do not; but if the fever is sufficient to depress the patient we use salicylates; if he is helped, the drug is continued; if not, it is stopped.

DR. F. S. DE LEE, Boston: I would like to ask Dr. Swift what the condition is of an individual who has rheumatism, recovers without drugs and on taking that again which was thought to be the cause of the

rheumatism, the rheumatism lights up, again—whether the rheumatism was lighted up by improper eating; whether the food was the entire cause and whether the individual on shutting off his salicylates and returning to his home did not produce rheumatism by the first cause. I presume you consider every case of rheumatism infectious?

DR. SWIFT: That is my conception of the disease. This conception of the disease is open to alteration at any time sufficient positive proof is presented: I do not regard complete positive proof, however, as arising from a single case, but from a series, because the infection produces so many variations; from a three day disease to one lasting three years. The citation of any one individual to prove a point is hardly scientific; there should be enough cases to prove the contention.

DR. DE LUCE: Another question, about growing pains in rheumatic children—that it isn't necessary to have any fever. Would you consider the ordinary stiff neck, without fever as rheumatism?

DR. SWIFT: No, unless they had rheumatic fever before. I have, however, seen patients with other signs of activity of rheumatism, without fever.

DR. DE LUCE: You may have rheumatic hearts without fever?

DR. SWIFT: Yes.

A MEMBER: Dr. St. Lawrence regards a level of 99.4 F. as normal; if it is below this point he regards the patient as afebrile and ready for discharge; what is Dr. Swift's practice?

DR. SWIFT: We consider 99.6 F. rectal temperature, as normal, as we have found that mouth temperatures are unreliable, especially if the patient has a weakened myocardium.

A MEMBER: Dr. Swift touched on the matter of tonsillectomy. I would like to ask if he takes out the tonsils routinely and if he does not, what are the criteria for removal of the tonsils?

DR. SWIFT: We do take out the tonsils routinely, because it seems to be the accepted practice. Some patients refuse operation and hence serve as controls. But we explain to all patients that tonsillectomy is only a part of the general treatment and that there is a possibility of relapse.

DR. E. H. PLACE, Boston: I would like to know if Dr. Swift takes out the tonsils during an active endocarditis and if so, whether there has been any unfavorable reaction; and whether there has been any lightening up shortly after the operation?

DR. SWIFT: I am glad that question has been brought up, because of our experience with relapses following tonsillectomy; although at present unable to give exact figures, I should judge that somewhere between 20 and 35 per cent. of our patients had shown signs of arthritis shortly after tonsillectomy and adenoidectomy. To evaluate this evidence properly, a similar series of patients should have undergone some other operation, in order to see if it is not merely the depression of operation that has brought about the relapses. Most of our patients have lost from three to nine pounds following tonsillectomy; this loss has occurred in spite of special effort on the part of our nurses to keep up a high caloric diet. I am of the opinion that a comparable loss of weight from any other cause would be followed by a certain number of relapses. In other words, many of our patients at the time of operation were harboring the virus, and the operation was the depressing factor that allowed it to become active.

A MEMBER: I would like to have Dr. Swift answer

Dr. Place's question whether he operates during acute symptoms.

DR. SWIFT: No; we have not; in view of the experience just cited we have felt it better to wait until the signs of activity had disappeared and the lost weight recovered. In this manner we hoped that the depressing influence of the operation would be less deleterious.

Original Article.

THE STING OF THE SEA-NETTLE.

By DOUGLAS H. STEWART, M.D., F.A.C.S., NEW YORK.

FROM page 158 of Wells' Chemical Pathology will be found the following sentence, "Many coelenterates produce active poisons, which have a paralyzing and a local irritant effect." It is to one of those coelenterates, named the sea-nettle, that attention is here called; because at the present time all the animals of the jelly-fish tribe are unusually abundant off the neighboring coasts (July, 1922). For reasons that we might describe as diplomatic the effects of the stings of the sea-nettle are Bonifacially classed in the "Ivy Poisoning" group, although in many instances the plants that produce such "poisoning" may not be within miles of the sufferer. Then, too, the pathological results and the clinical appearances of a "Dermatitis Venenata" differ materially according to a plant origin or that from the sting of a marine animal. Yet at the same time there are sufficient common manifestations to deceive the hasty and inattentive observer in his differentiation.

Information pointing to some sort of sting, experienced by some one who was bathing in salt water at the time, will suffice as an item with which to start a clear medical history.

Unfortunately for accuracy a child-victim will state that he has hurt his knee (for instance) when he has neither knowledge nor evidence of blow, contusion or fall; though he is endeavoring to say in his own way that something happened, so that his knee does not feel nor work as it should. Since the aforesaid was written the writer's attention has been called to two cases of adults who were stung while swimming under water. One was slashed across the mouth and chin and his rash would have been taken for a very severe and extensive grade of herpes febrilis. The other patient was slashed across both cheeks and nose and across the shoulders and back, with a rather prevailing erysipelatoid appearance to the wounds.

It would appear probable that the location of the sting mark depends upon the position of the victim's body when he is stung, *i.e.*, whether he is standing, sitting, wading, swimming, diving, etc. All that is emphasized in this place is that granted a good contact with the tendrils of a healthy sea-nettle and the animal

may be relied upon to attend to the business of stinging. The poison of the *Rhus* is a glucoside or toxicodendric acid, while the poison of the sea-nettle is akin to, or identical with, formic acid, though mixed with other substances. The *Dermatitis Venenata* of the *Rhus* presents redness, swelling and sometimes a diffuse edema; while the *Dermatitis Venenata* of the sea-nettle's sting produces a condition that might be considered to resemble a dermatocellulitis. It is, however, really an edema the edges of which are as clearly drawn as though marked out by a pencil. Or those edges are as well defined, to the observer's sense of touch, as are the margins of a piece of slate. Blistering, herpes, etc., are seen in either or both forms of *Dermatitis*.

The marks that the stings leave upon the skin of the victim are often found upon the outside of the lower extremity where they run or trend more or less vertically from the middle of the leg to the middle of the thigh. This is theoretically accounted for by the animal's body coming in contact with the upright body of its victim and, since the stinging tendrils hang more or less directly downward in the water, they come into good contact with the outside of the victim's leg. On the contrary should the animal's body be pushed aside by the hand as in the motion of swimming, or should that body come into contact with more or less protuberant or projecting abdomen or hips then the tendrils will swing free without contact, and no sting ensues. When stings are scored upon the arms or face the actual contact areas are often small; hence the amount of damage is limited, or trivial and is prone to be herpetiform in character. When, however, the contact-area runs from ankle to hip, then the irritative result that is provoked is very evident to all concerned.

The writer's observations lead him to think that the long, broad mark often found upon the leg is the result of contact with two or three tendrils; while an arm, for instance, might come into contact with but a portion of a single tendril. Therefore the mark found upon such an arm may resemble a welt, wheal, urticaria or herpes of small circumscribed extent; while a similar mark upon the leg is a more or less perfect rectangle, one or two inches in width and from six to eight inches in length. Upon one occasion several physicians were asked to furnish an appropriate description of the appearance left after a severe sting. The opinion was that it most closely resembled a commencing cellulitis (pulse and temp. normal). After two days the resemblance was lost, as the skin became dark brown in color and the corneous layer was destroyed quite as though there had been a second degree burn or a scald with a blister.

Children appear to suffer the most from after-effects possibly because of tender skins and because the poisonous dose is large in proportion

to body-weight. If lameness be manifested it will not amount to more than the difficulty in walking that follows ordinary contusion, for it has nothing to do with the actual condition of the articulation itself. The severity of result depends upon the condition of the victim and of the sea-nettle. A well tanned, thick, weather-beaten skin furnishes a high resistance; and temperature of water and the usual laws, that apply to greater or less activity of venoms in general, probably have their effect on the animal's efficiency.

The most commonly employed (and perhaps the least valuable) applications to a formic acid sting are the Tincture of Iodine and ordinary Alum Acetate solution. The most popular, most efficient and perhaps the most dangerous in its possibilities is a plastering of clay mud. Nothing better fills all the therapeutic indications than a compress kept constantly moistened with a two per cent. solution of Bicarbonate of Soda. A two per cent. solution of Phenol may be painted on for its analgesic effect, may be allowed to dry uncovered and then the Sod. Bicarb. compress may be employed over all, without fear of producing the well-known carbolic gangrene. In short, the attendant will do no damage if he bears in mind that the main object in this instance is to neutralize an acid with a non-irritating alkali (lime water, milk of magnesia, etc.). Perhaps the writer insists rather strongly on this because a personal experience with strong formic acid leads him to think that it would be difficult to imagine anything more painful in application, more irritating in its local effect, or producing a more intractable form of ulceration.

All sorts of legends of the "Once upon a time" variety are current along the beaches and refer to some vigorous swimmer being incapacitated and drowned, sinking to the bottom at once as the result of being paralyzed by the sting of a powerful sea-nettle. Whether there is the slightest truth in any such rumor is an open question. The writer's own experience would tend to show that in a tide run or among waves the position of a swimmer's body is such that the hanging stinging tendrils of the animal hang below the swimmer and are not so very apt to come in contact, whatever the two bodies may do, and at the same time the movement of the water itself would carry the swimmer and the animal apart in a very short interval of time. On the other hand where or when the water was sluggish with slow current (or none) as in pools, eddys, salt-marshes, etc., the chances for prolonged contact and marked sting-results are greater. It may be that just because children play in such quiet waters that they seem to be the most usual victims.

It should not be forgotten that the poison of the sea-nettle is a paralyzer in one sphere of its action. The paralyzing effect is always there;

but as to there being any real danger to a child or adult all the writer can say is there is a lot of truth in a maxim of Arago's which states: "Aside from the realm of pure mathematics he who uses the word 'Impossible' lacks prudence." That the sea-nettle can sting is easily proved, the only question unanswered is the extent of the damage of which the animal is capable under circumstances that are favorable to the stinger.

In conclusion it might be well to mention that if an observer will but pass his hand beneath some floating jelly-fish he will be able to select from among the number those that sting and those that do not sting. Practically, a screen of so-called chicken wire, even though it be attached to floats by its upper margin and have a couple of feet or so submerged, will form a barrier against the entrance of jelly-fish to any given enclosure of water, that may be used for the amusement of children.

Book Reviews.

A Manual of Diseases of the Stomach. By WILLIAM MACLENNAN, M.B., Honorary Consulting Physician, Western Infirmary, Glasgow, etc.; with the assistance of J. SALISBURY CRANIG, M.B., Ch.B. London: Edward Arnold. 1921. First edition. New York: Longmans, Green & Co. 380 pages, with many illustrations. Price, \$7.50.

This author has aimed at a book midway between the small manual type and the large, pretentious work adapted chiefly to the specialist. On the whole he has succeeded pretty well in turning out a useful, comprehensive and well-arranged volume covering pretty much the field of gastro-intestinal disease.

The work is divided into four distinct sections, the first covering anatomy, physiology and chemistry, with clinical and laboratory methods; the second, organic disease of the stomach; the third, functional disease, and the fourth, stomach symptoms in relation to disease of other organs, with a glossary of chemical and clinical tests.

It is inevitable in a book of these pretensions that in the mind of any reviewer certain parts should be unduly elaborated at the expense of others, and here 33 pages on test meals as against approximately the same number of pages on a subject as important as gastric ulcer seems a little out of balance. Furthermore, a modern book without reference to the Sippy method of management in peptic ulcer is a bit unusual.

The real recommendation for the book lies in the fact that it contains in compact form between two covers a collection of generally sound, well-arranged information covering the field of gastro-enterology. The therapeutic side is tolerably well done, and prescriptions and diet lists are well elaborated.

This should prove a useful book for students and a convenient reference to practitioners.

Manual of Physio-Therapeutics, by Thomas Davey Luke, M.D., F.R.C.S., Ed. Formerly Physician, Peebles Hydropathic, Peebles, N. B., Assistant Physician, Smedley's Hydropathic, Matlock; Sometime Lecturer at the Edinburgh University; Author of "Spas and British Health Resorts," etc., etc. With many illustrations. New and revised edition.

"Would you have us place reliance
Less in drugs and pseudo science?
More in Nature; for our ills
Using sense and fewer pills:
No—the change were all too tragic,
Most folks like being healed by magic."—*Anonymous*.

New York: William Wood and Company, 1922.

Mr. Luke's "Manual of Physio-Therapeutics" is exactly what its name implies, including under the term "A Section on Diet in the Treatment of Disease," Thermo-therapy, Hydro-therapy, Masso-therapy, The Rest Cure, Electro-therapeutics and Diet-therapy are separately discussed in sections. The book is profusely illustrated and very readable, with frequent touches of quaint humor. The author discloses a very wide experience with the technical details of Physio-therapeutic methods employed in the European Spas, especially those of Great Britain. The description of apparatus and the technique of application will prove of great practical usefulness to the Physio-therapist. That he is a firm believer in the value of these is evident. The knowledge and review of contributory literature is extensive.

The book may be unconvincing to the pure scientist, and seem to the general practitioner perhaps too optimistic as to the great benefit to be expected in a wide variety of serious ailments, but the precautions and contra-indications are so clearly stated that no harm is likely to result.

The experience of the War has strongly suggested that a scientific application of these methods will probably result in an earlier return of function and in an alleviation of suffering in many types of disease and lesions.

We commend the book to the student or practitioner of physio-therapeutics. The general practitioner is likely to have his interest in this subject definitely stimulated.

SUBSCRIPTION TERMS: \$6.00 per year in advance, postage paid for the United States, \$7.50 per year for all foreign countries belonging to the Postal Union.

Material for early publication should be received not later than noon on Saturday. Orders for reprints must be sent to the printer with galley proof of paper. Upon written request, authors will be furnished free one hundred eight-page reprints, without covers, or the equivalent in pages in articles of greater length.

The Journal does not hold itself responsible for statements made by any contributor.

Communications should be addressed to The Boston Medical and Surgical Journal, 126 Massachusetts Ave., Boston, Mass.

THE LETTER OF HENRY D. NUNN, ESQ., MANAGER AND GENERAL COUNSEL OF THE MEDICAL LIBERTY LEAGUE.

THE JOURNAL is ready to give space to a courteous letter, but we feel that the explanation appearing in another column does not explain the charge that "most physicians take vaccination purely on faith" as the term is commonly used. If the critic will state that most physicians have a firm belief in the doctrine that vaccination by cow pox virus, so called, prevents and modifies smallpox the JOURNAL will agree with him, but if he uses the Bible definition of faith as "the substance of things hoped for, the evidence of things not seen," we shall continue to feel that the position and standing of the profession is not properly portrayed. Faith founded on study, observation and reliable testimony is the foundation of the practice of medicine. We do not speak slurringly of the decision of a court because the testimony presented in a trial deals with the statement of facts and opinions of those testifying, and no one should assume that physicians base attitude and procedure on general unsupported statements.

It is, of course, true that a medical student accepts the teaching of his professors but with the reservation of the right to form his own opinions after having acquired maturity of judgment founded on experience. Any assertion that tends to convey the idea that he continues to

have blind adherence to the teaching of his student days does not apply to the great mass of practitioners. Almost immediately upon entering practice he puts his instruction to test and accepts or rejects the doctrines taught, in accordance with experience and testimony. The great majority of medical students of today have trained minds and are eagerly searching for demonstrated truths. Medicine is becoming more scientific with startling rapidity and the inelastic and provincial minds of some practitioners of a generation ago are being rapidly eliminated. The younger practitioner must of necessity satisfy himself of the truth or falsity of the statements previously made and if he does not come in contact with smallpox, he finds that every epidemic of this disease spreads unless checked by vaccination. He finds that every up-to-date board of health and health officer having been in contact with smallpox emerges from the conflict endorsing vaccination. If he personally has the opportunity of seeing smallpox cases he finds that the teaching of believers in vaccination is sustained by his experience.

Skepticism of the merits of vaccination should be generally resented by the medical profession for the profession as a body believes in vaccination and physicians do not relish the implication that an accepted belief is false nor the many other statements which have been made from time to time imputing selfish motives and alleging the disproportionate dangers of vaccination. The illustration of the contention of the correspondent based on the attitude of the "erstwhile president of a medical association" is not apt, for although this surgeon had early in life formed an opinion it is evident that he had found no occasion for changing that opinion. Why should he keep informed of the technical details of the production of vaccine? He uses antiseptic and sterile material in his work but he may be very much like many other surgeons who find no occasion to burden their minds with details of manufacture of these products. If he should find an abnormal percentage of sepsis among his cases he would find out the reason. Any physician who found smallpox as prevalent among the vaccinated as the unvaccinated would carefully study all factors involved and would confer with his associates with the purpose of finding the truth, *i.e.*, if his experience led him to feel that the claims made of the efficacy of vaccination are false he would readjust his attitude.

The protective power of vaccination is demonstrable, we believe. If our friends of the opposition wish to make an effective study of the problem let them take one hundred unvaccinated children and place them in contact with smallpox cases and, for control, subject one hundred other children who have been successfully vaccinated to the same association. This matter can be dealt with in a way to convince any fair-minded person.

Recently some objectors to compulsory vaccination have simply argued that all that they wish is abolishment of the *compulsory* feature of the law, but men with the same object in view are apt to be found associated and these less vigorous opponents of vaccination are found to be associated with those who earlier wanted to do away with vaccination altogether, and who talked about the spread of syphilis and the maimed and dead children following vaccination. If there are so many physicians who, if "candid," would admit having given no thought to the question of vaccination as claimed by the correspondent then there is a fertile field for the antivaccinationists to cultivate. We earnestly urge that this alleged great proportion of the medical profession be interviewed. It would be interesting to have them tabulated so that both proponents and opponents might know the approximate number of physicians who have no convictions on this subject.

The medical profession is under a solemn obligation to protect those in danger of disease who cannot protect themselves. If it was not for this duty the profession might be excused if the unpleasant features of controversy were abandoned. We are very like an army bearing sueror to a threatened city; so far as we have ability, adherence to duty is demanded in the name of humanity.

No convincing arguments have yet been advanced which would justify retreat.

methods designed to do away with the evils of drug addiction but when the Government taxes physicians engaged in ethical practice for the purpose of providing it with funds for protecting the people from harmful drugs it might go much further and levy a special tax on the surgeons' knives because some persons use knives in taking life. The registration of physicians with the right conferred to use narcotic drugs is logical, but the revenue tax is abhorrent and should be repealed. Doctors have contributed inestimable services to the nation and individuals and about all the public reward bestowed is exemption from jury duty. The degree of ability and industry exhibited by physicians, if applied in other walks of life, would average larger returns than those enjoyed by physicians and yet we must be taxed. Lawyers are not taxed to create a revenue which could be applied to controlling the shyster or any other class of criminals, but doctors are complacent and submit to exactions which are unjust.

As laws are enacted in the future the attitude and activity of the newly created legislative body of the A. M. A. will be watched with interest. We have not been able, as individuals, to protect ourselves. Will our representatives be more efficient?

NEWS ITEMS.

PROF. HARVEY CUSHING'S VISIT.—Prof. Harvey W. Cushing, who delivered the Cavendish lecture on Meningiomas last Tuesday evening before the West London Medico-Chirurgical Society, returned to America the next day, after acting for a fortnight as Director of the Surgical Unit at St. Bartholomew's Hospital. Some years ago when the Peter Bent Brigham Hospital at Boston, Mass., was founded in association with Harvard University, arrangements were made for exchange of visits by distinguished foreign surgeons, the visiting surgeon to be temporary surgeon-in-chief in place of Prof. Cushing for some period in each year. Prof. G. E. Gask deputised at Harvard in the spring of 1921, and Sir Cuthbert Wallace has just returned from filling a similar office. Although recognized as the leading neurological surgeon in the world, Prof. Cushing did not operate while he was in this country, but spent his time in observing methods of instruction, talking to students, and teaching in the out-patient and casualty departments of the hospital. His association with British surgeons during the war and the knowledge then acquired of the ways and manners of British sick and wounded made it possible for him to enter at once fully into the life of an English hospital. Our own surgeons envied Harvard its abundance of surgical assistants and its organization of type-

A FEATURE OF THE HARRISON NARCOTIC ACT.

In a decision of the Supreme Court written by Chief Justice Taft in denying a writ of error based on the charge that the indictment failed to charge that certain defendants sold inhibited drugs knowing them to be such, the court reversed the judgment of a lower court. The explanation is given that the statute does not make such knowledge an element of the defense. "Again where one deals with others and his mere negligence may be dangerous to them as in selling diseased food or poison the policy of the law may, in order to stimulate proper care, require the punishment of the negligent person though he be ignorant of the noxious character of what he sells."

In the opinion it is further stated, "The Narcotic Act has been held by this Court to be a taxing act with the incidental purpose of minimizing the spread of addiction."

This last exposition of the law sustains the interpretation which physicians have made. We are *taxed* for the right to use therapeutic agents. Because others make improper use of these agents is no valid reason why the Government, in all fairness, should impose a tax for revenue. All right minded physicians endorse all proper
